Note

Of the essays forming this volume, some two or three are now published, in English, for the first time. The remainder have appeared, at different times, in newspapers and magazines, including the Fortnightly Review, Harper's Magazine, the Atlantic Monthly, the Critic, the International Quarterly, the Daily Mail, and others. The thanks of the author and translator are due to the proprietors and editors of these periodicals for their leave to republish in the present volume.

THE MEASURE OF THE HOURS

I

SUMMER is the season of happiness. When, among the trees, in the mountains or by the sea, the fair hours of the year, the hours for which we have waited and hoped since the depths of winter, the hours which at last open to us the golden gates of leisure, return for our delight, let us learn to enjoy them fully, continuously, voluptuously. Let us have for these privileged hours a nobler measure than that into which we pour the ordinary hours. Let us gather their dazzling minutes in unaccustomed urns, glorious, transparent and made of the very light which they are to contain, even as we serve a costly wine not in the common glass of the daily table, but in the purest cup of crystal and silver locked in the sideboard of the banqueting-room.

II

The measuring of time! We are so constructed that we cannot be made conscious of time and impressed with its joys or sorrows unless we count and weigh it, like an invisible currency. It takes shape, acquires its substance and its value only in complicated forms of apparatus which we have contrived in order to render it apparent; and, having no existence in itself, it borrows the taste, the perfume and the shape of the instrument that rules it. For this reason, the minutes ticked off by our little watches wear a different aspect from those prolonged by the great hand of the belfry or cathedral-clock. It behoves us, therefore, not to be indifferent to the birth of the hours. Even as we have glasses whose shape, shade and brilliancy vary according as they are called upon to carry to our lips light claret or rich burgundy, cool hock or heavy port, or the gladness of champagne, why should not our minutes be numbered in ways appropriate to their melancholy, their inertness or their joy? It is fitting, for instance, that our working months and our winter days, days of bustle, business, hurry and restlessness, should be strictly, methodically, harshly divided and registered by the metal wheels and hands and the enamelled faces of our chimney-clocks, our electric or pneumatic dial-plates or our small pocket-watches. Here, majestic time, the master of gods and men, the immense human form of eternity, is no more than a stubborn insect gnawing mechanically at a life devoid of horizon, sky or rest. At most, at the warning moment that precedes the stroke, during the too-short evening snatched, under the lamp, from the cares of hunger or vanity, will the great copper pendulum of the Dutch or Norman clock be allowed to make slower and more

XXI

For all that touches upon our moral life, we still have the choice of our illusions: good sense itself, that is to say the scientific spirit, is obliged to admit as much. Wherefore, taking one illusion with another, let us welcome those from above rather than those from below. The former, after all, have brought us to the stage at which we are; and, when we look back upon our starting-point, the dreadful cave of prehistoric man, we owe them a certain gratitude. The latter illusions, those of the inferior regions, that is to say of good sense, have given proofs of their capacity hitherto only when accompanied and supported by the former. They have not yet walked alone. They are taking their first steps in the dark. They are leading us, they say, to a regular, assured, measured, exactly-weighed state of well-being, to the conquest of matter. Be it so: they have charge of this kind of happiness. But let them not pretend that, to attain it, it is necessary to fling overboard, like a dangerous cargo, all that hitherto formed the heroic, cloud-topped, indefatigable, adventurous energy of our conscience. Leave us a few fancy virtues. Allow a little space for our fraternal sentiments. It is very possible that these virtues and sentiments, which are not strictly indispensable to the just man of today, are the roots of all that will blossom when man shall have accomplished the hardest stage of the "struggle for life." Also, we must keep a few sumptuary virtues in reserve, in order to replace those which we abandon as useless; for our conscience has need of exercise and nourishment. Already we have thrown off a number of constraints which were assuredly hurtful, but which at least kept up the activity of our inner life. We are no longer chaste, since we have recognised that the work of the flesh, cursed for twenty centuries, is natural and lawful. We no longer go out in search of resignation, of mortification, of sacrifice; we are no longer lowly in heart or poor in spirit. All this is very lawful, seeing that these virtues depended on a religion which is retiring; but it is not well that their places should remain empty. Our ideal no longer asks to create saints, virgins, martyrs; but, even though it take another road, the spiritual road that animated the saints must remain intact and is still necessary to the man who wishes to go further than simple justice. It is beyond that simple justice that the morality begins of those who hope in the future. It is in this perhaps fairy-like, but not chimerical part of our conscience that we must acclimatise ourselves and learn to delight. It is still reasonable to persuade ourselves that in so doing we have not been duped.

THE MEASURE OF THE HOURS

contradict this idea, but serves to define and declare it. Even Bernini—rhetorical, exuberant, ubiquitous Bernini—as irreconcilable as it is possible to be with the primitive gravity and taciturnity of Rome, even he, so detestable elsewhere, seems here to be adopted, justified by the genius of the city and serves to explain and illustrate certain somewhat redundant and declamatory sides of Roman greatness.

Moreover, a city that possesses the *Venus* of the Capitol and of the Vatican, the *Sleeping Ariadne*, the *Meleager* and the *Torso of Hercules*, the countless marvels of museums as numerous almost as her palaces—think only of the treasures in a single one of these museums, the newest of all, the Nazionale—a city whose every street, almost every house conceals some fragment of marble or bronze which, did some new town contain it, would send pilgrims flocking; a city that can offer the Pantheon of Agrippa, certain columns in the Forum, in a word, so many treasures that baffled memory cannot keep pace with untiring admiration; a city that has among its wonders those cypress-girdled lawns of the Villa Borghese, those fountains, those eternal gardens; a city, indeed, that is the refuge of all that was best in the past of the only people who cultivated beauty as others cultivated corn, the olive or the vine: such a city opposes a resistance to vulgarity which, inactive though it be, is yet invincible; and she can tolerate all things without defilement. The immortal presence of an assembly of gods, so perfect that no mutilation can alter the rhythm of body or pose, protects her against the errors herself may commit and prevents the new generations of men from having more empire upon her than time and the barbarians had on those very gods.

And these lead us back to the little cities of Hellas that discovered one day and fixed for ever the laws of human beauty. The beauty of the earth, except for some spots which our sordid industries have ravaged, has altered but little since the days of Augustus and Pericles. The sea is infinite still, is still inviolate. The forest, the plain, the harvest, the villages, rivers and streams, the mountains, the dawn and the evening, the stars and the sky, vary as these all may according to climate and latitude, offer us still the same spectacles of grandeur and tenderness, the same soft, profound harmonies, the same fairy-like scenes of changing complexity which they showed to the Athenian citizens and the people of Rome. Nature remains more or less as she was; and, besides, we have grown more sensitive and can to-day admire more freely. But, when we turn to the beauty special to man, the beauty that is his own immediate aim, we find that, owing perhaps to our too great wealth or excessive application, to the scattering of our efforts, our lack of concentration, or the want of a certain goal and an incontestable starting-point, we appear to have lost almost all that the ancients had been able to establish and make their own. In all that regards purely human aesthetics, in what concerns our body, our gestures, our clothes, the objects we live

THE MEASURE OF THE HOURS

with, our houses and gardens, our monuments, even our landscapes, we are groping so timidly, we display such confusion and inexperience that one might truly believe our occupation of this planet to date but from yesterday and ourselves to be still at the very beginning of the period of adaptation. For the work of our hands there no longer exists a common measure, an accepted rule or conviction. Our painters, our architects, our sculptors, our men of letters—and we in our homes, our cities—seek in a thousand different, contradictory directions for the sure, the undeniable beauty which the ancients possessed so fully. Should one of us, by any chance, create, join together or discover a few lines, a harmony of form or colour that should incontestably prove that the mysterious, decisive point had been attained, it would be regarded as the merest hazard, as an isolated and precious phenomenon and neither the author nor any one else would be able to repeat it.

And yet, for a few happy years, man had mastered the laws of the beauty that is essentially and specifically human; and so great was his certainty that it compels our conviction even to this day. In the beauty of his own body, the Greek instinctively found the fixed standard which the Egyptians, the Assyrians, the Persians and all the anterior civilisations had sought in vain among animals and flowers, rocks and mountains, monsters and chimeras; and the architecture of his temples and palaces, the style of his houses, the proportion and ornament of the things which he used in his daily life were all derived from the beauty of this nude and perfect body. This people, among which nudity, with its natural consequence, the irreproachable harmony of limbs and muscles, was almost a religious and civic obligation, has taught us that the beauty of the human body is as diverse in its perfection, as spiritual, as mysterious as the beauty of the stars or sea. Every other ideal has misled and must always mislead the endeavours and efforts of man. In all the arts, intelligent races came nearer to true beauty in proportion as they came nearer to the habit of nudity; departing from this, they departed also from beauty. The beauty proper to Rome—in other words, the little original beauty which she added to the spoils of Greece—was due to the last remains of this custom. For, in Rome, as Taine tells us, “they also assembled together to swim, to be rubbed, to perspire, to wrestle and run; or at least, to watch the runners and wrestlers. For Rome, in this respect, is only an enlarged Athens; the same ways of life obtain, the same habits, the same instincts and pleasures: the only difference lies in the proportion and the moment. The city has swollen till it numbers masters by the hundred thousand and slaves by the million; but, from Xenophon to Marcus Aurelius, the gymnastic and rhetorical training has not altered; they have still the tastes of athletes and orators and it is in this direction that one must work to please them; they are worshippers of the nude, they are judges of style, of conversation and ornament. We can no longer understand this pa-

THE MEASURE OF THE HOURS

gan life of the body, which was so curious and yet so idle; the climate has remained as it was, but man changed when he put on clothes and turned Christian.”

It might more justly be said, perhaps, that Rome, at the period of which Taine speaks, was an intermittent and incomplete Athens. What was habitual there and, in some measure, organic becomes here only artificial and exceptional. They still cultivate and admire the human body, but it is almost always concealed by the toga; and the wearing of the toga blurs the pure, clear lines which a multitude of nude and living statues imposed upon the columns and pediments of the temples. The monuments grow larger and larger, lose their form and, little by little, their human harmony. The golden standard is shrouded and the veil shall be lifted only by a few artists of the Renaissance, which was the moment when positive beauty shed its last beams.

THE PSYCHOLOGY OF ACCIDENT

I

THE more we master the forces of nature, the more do our chances of accidents multiply, even as the tamer's dangers increase in proportion to the number of wild animals which he “puts through their tricks” in the cage. Formerly, we avoided the contact of these forces as much as possible; to-day, they have gained admittance to our household. And so, notwithstanding our more prudent and peaceable manners, it happens to us more often than to our fathers to look pretty closely upon death. It is probable, therefore, that many of those who read these notes will have felt the same emotions and have had occasion to make similar remarks.

II

One of the first questions that arises is that of presentiment. Is it true, as many assert, that from the very morning we have a sort of intuition of the event that threatens the day? It is difficult to reply, inasmuch as our experience can bear only upon events which “might have turned out worse,” or which, at least, have had no serious results. It seems natural, therefore, that those accidents which were to be free from consequences should not have stirred the deep waters of our instinct beforehand; and I believe it to be true that they do not even ripple their surface. As for the others, which entail a more or less speedy death, their victims seldom possess the strength or lucidity required to satisfy our curiosity. In any case, all

THE MEASURE OF THE HOURS

that our personal experience is able to gather on this subject is very uncertain; and the question remains.

III

One fine day, then, we start at early dawn, by motor-car, bicycle, motor-cycle, in a skiff or steam-boat: it is immaterial to the event that is preparing; but, to make the picture more definite, let us take, by preference, a motor-car or motor-cycle, which are wonderful instruments of affliction and which put the fiercest questions to fortune in the great game of life and death. Suddenly, for no reason, at the turn of the road, in the very middle of the long, wide highway, at the top of a descent, here or there, on the right or on the left, seizing the brake, the wheel, the steering-handle, unexpectedly barring all space, assuming the deceptive and perfectly transparent appearance of a tree, a wall, a rock, an obstacle of one sort or another, stands death, face to face, towering, unforeseen, huge, immediate, indubitable, inevitable, irrevocable, and, with a click, shuts off the horizon of life, which it leaves without outlet. . . .

Forthwith, an eager and interminable scene, contained within half a second, sets in between our intelligence and our instinct. The attitude of our intelligence, our reason, our consciousness, by whatever name you please to call it, is extremely interesting. It decides instantaneously, sanely and logically that all is irretrievably lost. Yet it displays neither madness nor terror. It pictures the catastrophe, with all its details and consequences, exactly; and it realises with contentment that it is not afraid and that it preserves its lucidity. Between the fall and the collision, it has time to rest, it reflects, it diverts itself, it finds leisure wherein to think of all manner of other things, to call up memories, to make comparisons, trifling and accurate observations: the tree which we see through death is a plane-tree, there are three holes in its patterned bark. . . . It is not so fine as the one in the garden. . . . The rock on which our skull will be broken is veined with mica and very white marble. . . . Our intelligence feels that it is not responsible, that we have nothing to reproach it with; it is almost smiling, it enjoys an ambiguous sensation of pleasure and awaits the inevitable with a tempered resignation mingled with prodigious curiosity.

IV

It is evident that, if our lives had only the intervention of this indolent, this too-logical and too-clearsighted dilettante to rely upon, every accident would be fated to end in disaster. Luckily, warned by

THE MEASURE OF THE HOURS

the nerves, which whirl, lose their heads and bawl like terrified children, another figure bounds upon the stage, a rugged, brutal, naked, muscular figure, elbowing its way and seizing with an irresistible gesture such remnants of authority and chances of safety as come within its reach. We call it instinct, the unconscious, the subconscious: it matters not what we call it. Where was it? Where does it come from? It was somewhere asleep or else busied with dingy and thankless tasks deep down in the primitive caverns of our body. Once it was that body's uncontested king, but, for some time since, has been relegated to the lower darkness as an ill-bred, ill-dressed, ill-spoken poor relation, a troublesome and often disagreeable witness of our original misfortune. We no longer think of it, no longer have recourse to it, save in the desperate seconds of our supreme anguish. Fortunately, it has a decent nature, is utterly unselfish and bears no grudge. Instinct knows, besides, that all those ornaments from the height of which we look down upon and despise it are ephemeral and frivolous and that, in reality, itself is the sole master of the human dwelling. With a glance that is surer and swifter than the tremendous onrush of the peril, it takes in the situation, then and there unravels all its details, issues and possibilities and, in a trice, affords a magnificent, an unforgettable spectacle of strength, courage, precision and will, in which unconquered life flies at the throat of unconquerable death.

V

This champion of existence, upstarting like the shaggy savage of the fairy-tales who comes to the rescue of the disconsolate princess, works miracles in the strictest, the most precise sense of the word. Above all, under pressure of necessity, it has one incomparable prerogative: it knows nothing of deliberation, of all the obstacles which it raises, all the impossibilities which it imposes. Instinct never accepts disaster, not for a moment admits the inevitable and, when on the point of being smashed to atoms, acts cheerfully against all hope, as though doubt, anxiety, fear, discouragement were notions absolutely foreign to the primitive forces that quicken it. Through a granite wall it sees nothing but safety, like a cranny of light; and, by dint of seeing it, creates it in the stone. It does not abandon the hope of stopping a mountain that is rushing down upon it. It thrusts aside a rock, darts upon a wire, slips between two columns which were mathematically too close together to admit its passage. Among trees, it chooses infallibly the only one that will yield because an invisible worm has gnawed its root; amid a cluster of vain leaves, it discovers the one strong branch that overhangs the abyss; and, in a heap of sharp flints, it is as though instinct had prepared in anticipation the bed of moss and ferns that is to receive the body. . . .

THE MEASURE OF THE HOURS

The danger once past, reason, stupefied, gasping for breath, unbelieving, a little disconcerted, turns its head to take a last look at the improbable. Then it resumes the lead, as of right, while the good savage, that no one dreams of thanking, returns in silence to its cave.

VI

Perhaps it is not surprising that instinct should save us from the great habitual and immemorial dangers: water, fire, falls, collisions, animals. There is here, evidently, a long custom, an ancestral experience to explain its skill. But what amazes me is the ease, the quickness wherewith it acquaints itself with the most complicated, the most unusual inventions of our intelligence. We have only, once and for all, to show it the mechanism, the use and the purpose of the most unexpected machine, however foreign and useless to our real and primitive needs: instinct understands; and, from that moment, in an exigency, it will know the machine's last secrets and its management better than does the intelligence which constructed it.

That is why, let the instrument be as new, as recent or as formidable as it will, we can safely say that, in principle, there is no such thing as an inevitable catastrophe. Our unconsciousness is always alive and equal to every imaginable situation. Between the jaws of the vice contained in the power of the mountain or the sea, we can, we must look for a decisive movement on the part of our instinct, which possesses resources as inexhaustible as those of the universe or of nature, upon whose stores it draws at will.

VII

And yet, if the whole truth be told, we no longer all have the same right to rely upon its sovereign intercession. It never dies, never sulks, is never mistaken; but many men banish it to such depths, so rarely permit it to catch a glimpse of sunlight, lose sight of it so entirely, humiliate it so cruelly, pinion it so closely that, in the madness of their dire need, they forget where to look for it. They have not the material time in which to warn it or to release it from the dungeon wherein they have chained it; and, when, at last, full of goodwill, armed with its tools, it hurries up to the rescue, the mischief is done, it is too late, death has completed its work.

These inequalities of instinct, which are connected rather, I suppose, with the promptness of the appeal rather than with the quality of the assistance, appear in every accident. Place two motorists in two parallel, ineludable and exactly identical cases of danger: an inexplicable touch of the wheel, a leap, a twist, a turn, a sheer quies-

THE MEASURE OF THE HOURS

cence, a spell of some kind will save the one, whereas the other will go his normal and wretched way and be smashed to pieces against the obstacle. Of the six persons in a car, all strictly involved in the same fate, three will make the only possible, illogical, unforeseen and necessary movement, while the three others will act with too much intelligence in the wrong direction. I once witnessed one of those surprising manifestations of instinct, or nearly witnessed it; for, although I arrived after the accident, at least I gathered the throbbing impressions on the spot, among the injured. It was on the descent from Gourdon, the rugged little village, well known to excursionists from Cannes and Nice, perched on a precipitous rock, over two thousand feet in height, to escape the Barbary pirates. It is inaccessible on every side; no thoroughfare leads to it, save a terrible zigzag way, which runs down between two ravines. A tilted cart, overloaded with eight persons, including a woman carrying her child not two months old, was descending this dangerous road, when the horse took fright, ran away and darted towards the abyss. The passengers felt themselves rushing to their deaths; and the woman, anxious to save the child and obeying an admirable impulse of maternal love, flung it, at the supreme moment, from the other side of the cart, where it fell on the roadway, while all the others disappeared in the precipice bristling with murderous rocks. Now, by a miracle which is not unusual where human lives are at stake, the seven victims, caught up in brushwood, in all manner of boughs, escaped with insignificant scratches, whereas the poor little child died where it fell, with its skull broken by a stone on the road. Two contrary instincts had here struggled for the mastery; and that one with which a glimmer of reflection had probably been mingled had made the more awkward movement of the two. You will speak of good and bad luck. These mysterious words are permissible, provided it be understood that they are applied to the mysterious movements of our unconsciousness. It is, in fact, preferable, whenever the thing is possible, to throw back the source of a mystery within ourselves: we thus limit to that extent the inauspicious field of error, discouragement and impotence.

VIII

We immediately ask ourselves whether we are able, if not to perfect our instinct, which I persist in believing perfect, at least to recall it closer to our will, to unloose its bonds, to restore its original freedom. This question would demand a special study. In the meantime, it appears fairly probable that, by drawing habitually and systematically closer to material forces and facts, to all that which, in a word that expresses enormous things, we call nature, we can diminish by so much daily the distance which instinct will have to cover

THE MEASURE OF THE HOURS

in order to come to our aid. This distance, as yet inappreciable in savages and in simple and humble men, increases with every step taken by our education and civilisation. I am persuaded that it could be proved that a peasant or workman, even if he be the less young and the less active, if overtaken by the same disaster as his squire or employer, has two or three chances more than the latter of escaping safe and sound. In any case, there is no accident of which the victim is not, *a priori*, in the wrong. It is meet that he should say to himself, what is literally true, that any other, in his place, would have escaped; consequently, the majority of the risks which those around him take remain forbidden to himself. His unconsciousness, which here blends with his future, is not "in form." Henceforth he must distrust his luck. From the point of view of the great dangers, he is a *minus habens*, as they used to say in Roman law.

IX

For all this, when we consider the lack of consistency of our body, the inordinate power of all that surrounds it and the number of perils to which we expose ourselves, our luck, compared with that of other living beings, must needs appear prodigious. In the midst of our machines, our various apparatus, our poisons, our fires, our waters, all the forces which we have more or less mastered, but which are always ready to rise in revolt, we risk our lives twenty or thirty times oftener than the horse, for instance, the ox or the dog. Now, in a street or road accident, in a flood, an earthquake, a storm, a fire, in the fall of a tree or a house, the animal will almost always be struck by preference to the man. It is obvious that the latter's reason, his experience and his more prudent instinct preserve him to a great extent. Nevertheless, one would say that there must be something more. Granting equal risks and hazards and allowing for intelligence and a more skilful and certain instinct, the fact still remains that nature seems to be afraid of man. She religiously avoids touching that frail body, surrounds it with a sort of manifest and unaccountable respect and, when, through our own arrogant fault, we oblige her to hurt us, she does us the least harm possible.

IN PRAISE OF THE FIST

I

IT is well, in the holiday season of summer, to occupy ourselves with the aptitudes of our body, once more restored to nature, and, in particular, with the exercises that most increase its strength, its

THE MEASURE OF THE HOURS

agility and its qualities as the body of a fine animal, healthy, formidable, ready to face all life's exigencies.

I remember, in this connection, that lately, when writing of the sword,¹ I allowed myself to be carried away by my subject and was guilty of a certain injustice towards the only specific weapon with which nature has endowed us: I mean the fist. This injustice I am anxious to repair.

The sword and the fist form each other's complement and, if the expression be not too ungracious, can keep house together on excellent terms. But the sword is, or should be, only an exceptional weapon, a sort of *ultima et sacra ratio*. We should not have recourse to it save with solemn precautions and a ceremonial equivalent to that wherewith we surround those criminal trials which may end in a sentence of death. The fist, on the contrary, is preeminently the every-day, the human weapon, the only weapon organically adapted to the sensibility, the resistance, the offensive and defensive structure of our body.

The fact is that, if we well examine ourselves, we must rank ourselves, without vanity, among the most unprotected, the most naked, the most fragile, the most brittle and flaccid beings in creation. Compare us, for instance, with the insect, so formidably equipped for attack and so fantastically armour-cased! Contemplate, among others, the ant, upon which you may heap ten or twenty thousand times the weight of its body without apparently inconveniencing it. Consider the cockchafer, the least robust of the beetles, and weigh what it is able to carry before the rings of its abdomen crack or the casings of its forewings yield. As for the resistance of the stag-beetle, it is, so to speak, unlimited. By comparison, therefore, we and the majority of mammals are unsolidified beings, still in the gelatinous state and quite close to the primitive protoplasm. Our skeleton alone, which is as it were the rough sketch of our definitive form, offers a certain consistency. But how wretched is this skeleton, which one would think constructed by a child! Look at our spine, the basis of our whole system, whose ill-set vertebrae hold together only by a miracle, and our thoracic cage, which presents only a series of diagonals which we hardly dare touch with the finger-tips. Now it is against this slack and incoherent machine, which resembles an abortive effort of nature, against this pitiful organism, from which life tends to escape on every side, that we have contrived weapons capable of annihilating us even if we possessed the fabulous armour-case, the prodigious strength and the incredible vitality of the most indestructible insects. We have here, it must be agreed, a very curious and a very disconcerting aberration, an initial folly, peculiar to the human race, that goes on increasing daily. In order to return to the natural logic followed by all other living beings, if we are permitted to use extraordinary weapons against our enemies of a different order, we ought, among ourselves, among men, to employ

THE MEASURE OF THE HOURS

only the means of attack and defence provided by our own bodies. Were mankind to conform strictly to the evident will of nature, the fist, which is to man what its horns are to the bull and its claws and teeth to the lion, the fist should suffice for all our needs of protection, justice and revenge. A wiser race would forbid any other mode of combat as an irremissible crime against the essential laws of the species. At the end of a few generations, we should thus succeed in spreading and putting into force a sort of panic-stricken respect of human life. And how prompt and how exactly in accordance with nature's wishes would be the selection brought about by the intensive practice of pugilism, in which all the hopes of military glory would be centred. Now selection is, after all, the only really important thing that claims our preoccupation; it is the first, the greatest and the most eternal of our duties towards the race.

II

Meanwhile, the study of boxing gives us excellent lessons in humility and throws a somewhat alarming light upon the forfeiture of some of our most valuable instincts. We soon perceive that, in all that concerns the use of our limbs—agility, dexterity, muscular strength, resistance to pain—we have sunk to the lowest rank of the mammals or the batrachians. From this point of view, in a well-conceived hierarchy, we should be entitled to a modest place between the frog and the sheep. The kick of the horse, the butt of the bull, the bite of the dog, are mechanically and anatomically perfect. It would be impossible to improve, by the most learned lessons, their instinctive manner of using their natural weapons. But we, the "Hominidae," the proudest of the primates, do not know how to strike a blow with our fist! We do not even know which exactly is the weapon of our kind! Look at two draymen, two peasants who come to blows: nothing could be more pitiable. After a copious and dilatory broadside of insults and threats, they seize each other by the throat and hair, make play with their feet, with their knees, at random, bite each other, scratch each other, get entangled in their motionless rage, dare not leave go and, if one of them succeed in releasing an arm, he strikes out blindly and most often into space a series of hurried, stunted and sputtering little blows; and the combat would never end if the treacherous knife, evoked by the shame of the incongruous sight, did not suddenly, almost spontaneously leap from the pocket of one of the two.

On the other hand, watch two pugilists: no useless words, no gropings, no anger; the calmness of two certainties that know what lies before them. The athletic attitude of the guard, one of the finest of which the male body is capable, logically exhibits all the muscles of the organism to the best advantage. From head to foot, not a par-

THE MEASURE OF THE HOURS

ticle of strength can now go astray. Every one of them has its pole in one or other of the two massive fists charged to the full with energy. And the noble simplicity of the attack! Three blows, no more, the fruits of secular experience, mathematically exhaust the thousand useless possibilities hazarded by the uninitiated. Three synthetic, irresistible, unimprovable blows. As soon as one of them frankly touches the adversary, the fight is ended, to the complete satisfaction of the conqueror, who triumphs so incontestably that he has no wish to abuse his victory, and with no dangerous hurt to the conquered, who is simply reduced to impotence and unconsciousness during the time needed for all ill-will to evaporate. Soon after, the beaten man will rise to his feet with no lasting damage, because the resistance of his bones and his organs is strictly and naturally proportioned to the power of the human weapon that has struck him and brought him to the ground.

III

It may seem paradoxical, but the fact is easily established that the science of boxing, in those countries where it is generally practised and cultivated, becomes a pledge of peace and gentleness. Our aggressive nervousness, our watchful susceptibility, that sort of perpetual state of alarm in which our jealous vanity moves, all these arise, at bottom, from the sense of our weakness and of our physical inferiority, which toil as best they may to overawe, with a proud and irritable mask, the men, often churlish, unjust and malevolent, that surround us. The more that we feel ourselves disarmed in the face of attack, the more are we tortured by the longing to prove to others and to persuade ourselves that no one attacks with impunity. Courage becomes the more touchy, the more intractable in proportion as our anxiously-terrified instinct, cowering within the body that is to receive the blows, asks itself how the bout will end. What will this poor prudent instinct do if the crisis goes badly? It is upon our instinct that we rely in the hour of danger. Upon our instinct devolve the anxiety of the attack, the care of the defence. But we have so often in daily life dismissed it from the control of affairs and from the supreme council that, when its name is called, it comes forth from its retreat like one grown old in captivity and suddenly dazzled by the light of day. What resolution will it take? Where is it to strike: at the eyes, the stomach, the nose, the temples, the throat? And what weapon is it to choose: the feet, the teeth, the hand, the elbow, or the nails? It no longer knows; it wanders about its poor dwelling, which is about to be defaced; and, while, dotingly, it pulls them by the sleeve, courage, pride, vanity, spirit, self-esteem, all the great and splendid, but irresponsible lords envenom the stubborn quarrel, which at last, after numberless and grotesque evasions, ends in an

THE MEASURE OF THE HOURS

unskilful exchange of clamorous, blind, ataxic thumps, hybrid and plaintive, piteous and puerile and indefinitely impotent.

He, on the contrary, who knows the source of justice which he holds in his two closed fists has no need for self-persuasion. Once and for all, he knows. Longanimity emanates like a peaceful flower from his ideal, but certain victory. The grossest insult cannot impair his indulgent smile. Peaceably he awaits the first act of violence and is able to say to all and any that offend him, "Thus far shall you go." A single magic movement stops the insolence. Why make this movement? He ceases even to think of it, so certain is its efficacy. And it is with a sense of shame, as of one striking a defenceless child, that, in the last extremity, he at length resolves to raise against the most powerful brute the sovereign hand that regrets beforehand its too-easy victory.

THE FORGIVENESS OF INJURIES

I

IT is not unprofitable to examine from time to time the meaning of certain words which clothe in an unchangeable garment thoughts that have themselves become transmuted.

To take for instance the word "forgive," which appears, at first sight, one of the most beautiful in the language: does this word still, did it ever possess the sense of almost divine amnesty which we assign to it? Is it not one of the terms that best set forth the good-will of men, inasmuch as it contains an ideal that has never been realised? When we say to one who has injured us, "I forgive you and all is forgotten," how much truth is there at the bottom of this speech? At most, this, which is the only engagement into which we can enter: "I shall not try to harm you in my turn." The remainder, which we believe ourselves to be promising, does not depend upon our own will. It is impossible for us to forget the wrong that has been done us, because the profoundest of our instincts, that of self-preservation, has a direct interest in remembering it.

The man who, at a given moment, finds his way into our lives is never known to us as he is. For us he is only an image which he himself outlines in our memory. It is quite true that the life that animates him has an indefinable, but powerful self-revealing face. It conveys a host of promises, which are probably deeper and more sincere than the words or actions that will ere long belie them. But this great sign has little more than an ideal value. We are in a world wherein, either through force of circumstances or as the result of an initial error, very few beings live in accordance with the truth which their presence there foretells. At long last, our fretful experience

THE MEASURE OF THE HOURS

teaches us to take no further account of this too mysterious face. A plain, hard mask covers it and bears the impress of all the acts and deeds that have affected us. Kindnesses illumine it with attractive and delicate colours, whereas offences channel it with deep grooves. In reality, it is only under this mask, modelled according to the recollection of pleasures or cares, that we perceive the man who approaches us; and to say to him, if he have offended us, that we forgive him is tantamount to telling him that we do not recognise him.

II

It is a question of knowing what influence this inevitable recognition will have upon our relations with the man who has injured us. In this, as in so many other respects, as soon as our good-will is roused, its first, as yet unconscious steps bring it back to the old road of the religious ideal. At the summit of this ideal, we might set up, as a symbol, the legendary group of the Christian woman burying, at the risk of her life, the execrated remains of Nero. There is no denying that the action of this woman is greater and goes farther beyond human reason than the action of Antigone, which dominates pagan antiquity. Nevertheless, it does not exhaust the limits of Christian forgiveness. Suppose that Nero be not dead, but staggering on the last confines of life and that an heroic rescue alone can save him. The Christian will owe him this rescue, even though she know for certain that the life which she is restoring to him will, at the same time, bring back the persecution. She can rise higher still: imagine that she have to choose in the same moment of anguish between her brother and the enemy who will doom her to destruction. She will reach the topmost summit only by preferring the enemy.

III

Of this ideal, which is sublime even where an infinite reward for it is taken into account, what are we to think in a world that looks for nothing in another world? At which of the three superhuman moments shall we call him mad who flings himself into one of those three abysses of forgiveness? We shall even to this day find a few traces of footsteps around the first; but no one will now stray around the two others. Let us admit that we have here a sort of heroic march of faith which is no longer possible; but, taking away faith, there nevertheless remains, even in the unreason of that ideal, something human that is as it were a presentiment of what man would like to do if life were not so cruel.

And let us not think that instances of this kind, taken from the

THE MEASURE OF THE HOURS

farthest ends of imagination, are idle or absurd. Existence constantly brings before us equivalents that are less tragic, but no less difficult; and the solution of the humblest cases of conscience depends upon the spirit which presides over that of the loftiest. All that we imagine on a large scale will end by being realised on a small; and upon the choice which we would make on the mountain depends exactly that which we will make in the valley.

IV

Moreover, we can learn to forgive as completely as the Christian. We are no more prisoners than he of this world which we see with the eyes in our head. We need only an effort similar to his, but directed towards other gates, in order to escape from it. The Christian, just like ourselves, did not forget the injury; he did not attempt the impossible; but he first proceeded to drown any desire for revenge in the divine immensity. This divine immensity, more closely considered, is not very different from our own. Both, in reality, are but the feeling of the nameless immensity wherein we struggle. Religion raised every soul mechanically, so to speak, to the heights which we ought to reach by means of our own strength. But, as most of the souls which it drew thither were as yet blind, it made no vain endeavour to give them an idea of the truths which we perceive from those heights. They would not have understood them. It contented itself with describing to them pictures appropriate and familiar to their blindness, pictures which, for very different reasons, produced nearly the same effects as the real vision that strikes us at present. "We must forgive offences because God wishes it and has Himself set the most complete example of forgiveness that it is possible to imagine." This command, which we can follow without opening our eyes, is exactly the same as that given to us by the needs and the profound innocence of all life at the moment when we contemplate them from a sufficient height. And, if this latter command does not, like the first, go so far as to urge us to prefer our enemy because he is our enemy, this is not to say that it is less sublime, but that it addresses hearts which are more distinterested and minds which have learnt no longer to appraise an ideal solely according as to whether it be more or less difficult of attainment. In sacrifice, for instance, in penance, in mortification, there are, in this way, a whole series of spiritual victories which are more and more painful, but which are not really higher, because they rise not in the human atmosphere, but in the void above, where they shine not only without necessity, but often in a very hurtful fashion. The man who juggles with balls of fire on the point of a steeple is also doing a very difficult thing; yet no one dreams of comparing his useless courage with the devotion, nearly always less dangerous though it be, of the man who flings

THE MEASURE OF THE HOURS

himself into the water or the flames to save a child. In any case—and perhaps more efficaciously than the other—the command of which we were speaking dispels all hatred, for it no longer springs from a foreign will, it is born within ourselves at the sight of an immense spectacle in which men's actions assume their real place and meaning. There is no more ill-will, ingratitude, injustice or perversity, there is not even any more selfishness, in the magnificent and boundless night wherein poor beings move, guided by a darkness which each of them follows in exceeding good faith, believing that he is fulfilling a duty or exercising a right.

V

Let us not fear lest this vision, together with so many others which are grander and no less exact and which should always be present to our eyes, let us not fear lest it should disarm us and make victims or dupes of us in a life of vaster and harsher realities. There are very few among us that have need to strengthen their means of defence, to whet their prudence, their mistrust or their selfishness. Life's instinct and experience provide for this but too lavishly. We are never in danger of losing our equilibrium on the side opposed to our petty daily interests. All the efforts of a watchful thought suffice only with great difficulty to keep us erect. But it is no matter for indifference to others and especially to ourselves whether our movements of attack and defence are outlined against the dull background of hatred, contempt and disenchantment or against the transparent horizon of indulgence and of the silent forgiveness that explains and understands. Above all, as the years pass, let us keep to the humble lessons of experience. There is in these lessons a dull and heavy part that belongs by right to instinct and descends to the necessary clay-soil of life. There is no need to occupy ourselves with it: it buds and multiplies prodigiously in the unconscious. But there is a purer and more subtle part which we must learn to catch and hold before it evaporates in space. Every act allows of as many different interpretations as there are diverse forces in our intelligence. The lowest of them appear at first the simplest, the most natural and just, because they are the first to come, the idlest, those requiring the least effort. If we do not struggle without respite against their cunning and familiar encroachment, little by little they devour and poison all the hopes, all the beliefs out of which our youth had formed the noblest and most fruitful regions of our mind. Soon there would remain to us, towards the end of our days, nothing but the most miserable residue of wisdom. It is meet, therefore, that the loftiest interpretation which we can give of the facts that hustle us at every moment should rise in proportion as the gross treasure of the practical sense of existence accumulates. According as our sense of life

THE MEASURE OF THE HOURS

increases in the soil by the roots, it is indispensable that it should ascend in the light by the fruits and flowers. It is necessary that an ever-vigilant thought should incessantly lift up, air and quicken the dead-weight of the years. Moreover, experience, seemingly so positive, so practical, so easy-going, so tranquil, so ingenuous and so sincere, knows full well that it hides some essential thing from us; and, had we the strength to drive it to its most secret retrenchments, we should end to a certainty by wringing from it the supreme avowal that, upon the upshot and when all and everything is said, the loftiest interpretation is invariably the truest.

CONCERNING "KING LEAR"

I

IT is easy to prove that, of late years and especially since the beginning of the great romantic period, the realm of poetry—which had hardly been touched upon since the definite loss of the vast, but uninhabitable provinces of the epic poem—has gradually shrunk in dimensions and become actually reduced to a few isolated towns in the mountain. It will probably continue there, long-lived and impregnable, and will gain in purity and intensity all that it has lost elsewhere in extent and abundance. Little by little it will strip itself of its vain didactic, descriptive and narrative ornaments, soon to be itself alone, that is to say the only voice that can reveal to us the things which silence hides from us, which human speech no longer utters and which music does not yet express.

Lyric poetry will always exist: it is immortal, because it is necessary. But what fate has the future or even the present in store, I will not say for the dramatist or playwright, but for the tragic poet proper, for the writer who strives to maintain a certain lyrical quality in his work by representing in it things greater and finer than the things of real life?

It is certain that the lyric tragedy of the Greeks, that classical tragedy as conceived by Corneille and Racine, that the romantic tragedy of the Germans and Victor Hugo all derive their poetry from sources that are definitely dried up. The great drama of the crowds, in which it was believed that an unknown and inexhaustible source had been discovered, has hitherto yielded only mediocre and indifferent results. And the new mysteries of our modern life, which have taken the place of all the others and in the direction of which Ibsen attempted certain excavations, these mysteries have been for too short a time in direct contact with man to erect and visibly and efficaciously to govern the words and actions of the character of a play. And yet there is no disguising the fact and the poetic instinct of hu-

THE MEASURE OF THE HOURS

manity has always felt its presentiment: a drama is not really true until it is greater and finer than life.

II

Let us, in the interval preceding the time when the poets shall know whither to turn their steps, examine one of the most famous examples of those dramas which enlarge the truth without violating it, one of those rare dramas which, after more than three centuries, still remain green and living in all their parts: I allude to Shakspeare's *King Lear*.

It is safe to declare, as I once said—not without some little exaggeration, for it is impossible to avoid exaggeration in the light and exquisite attack of fever which seizes all Shakspeare's devoted admirers whenever one of his masterpieces is revived—it is safe to declare, after surveying the literatures of every period and of every country, that the tragedy of the old king constitutes the mightiest, the vastest, the most stirring, the most intense dramatic poem that has ever been written. Were we to be asked from the height of another planet which is the synthetic and representative play, the archetypal play of the human stage, the play in which the ideal of the loftiest scenic poetry is most fully realised, it seems to me certain that, after due deliberation, all the poets of our earth, the best judges in this exigency, would with one voice name *King Lear*. They could only for a moment weigh the claims of two or three masterpieces of the Greek stage, or else—for virtually Shakspeare can be compared with none save himself—of that other miracle of his genius, the tragic story of *Hamlet Prince of Denmark*.

III

Prometheus, the *Orestes*, *Oedipus Tyrannus* are wonderful but isolated trees, whereas *King Lear* is a marvellous forest. Let us admit that Shakspeare's poem is less clear, not so evident, not so visibly harmonious, not so pure in outline, not so perfect in the rather conventional sense of the word; let us grant that it has faults as enormous as its good qualities: this fact none the less remains, that it surpasses all the others in the mass, the rarity, the density, the strange mobility, the prodigious bulk of the tragic beauties which it contains. I know that the total beauty of a work is not to be estimated by weight or volume; that the dimensions of a statue do not necessarily bear a relation to its aesthetic value. Nevertheless, it cannot be denied that abundance, variety and ampleness add certain vital, unaccustomed elements to beauty; that it is easier to be suc-

THE MEASURE OF THE HOURS

cessful with one statue of middling size and of a calm movement than with a group of twenty statues of superhuman dimensions, endowed with passionate and yet coordinate gestures; that it is less difficult to write one tragic and mighty act in which three or four persons play their parts than to write five which are filled with a whole moving crowd and which maintain that same tragic and powerful note on an equal level during a period five times as long as the other. Well, by the side of *King Lear*, the longest Greek tragedies are little more than plays in one act.

On the other hand, if we try to compare it with *Hamlet*, we shall probably find that its thought is less active, less acute, less profound, less quivering, less prophetic. By way of compensation, however, how much more vigorous, massive and irresistible does the spirit of the work appear! Certain clusters, certain rays of light on the platform of Elsinore reach and, for a moment, illumine, like gleams from beyond the tomb, more inaccessible darkneses; but here the column of smoke and flame lights up in a permanent and uniform manner a whole stretch of the night. The subject is simpler, more general and more normally human, the colouring more monotonous, but more majestically and more harmoniously superb, the intensity more constant and more widespread, the lyricism more continuous, more overflowing and more illusive and yet more natural, nearer to the realities of everyday life, more familiarly stirring, because it springs not from thought, but from passion, because it surrounds a situation which, although exceptional, is, nevertheless, universally possible, because it does not necessarily require a metaphysical hero like Hamlet and because it immediately affects the primitive and almost invariable soul of man.

IV

Hamlet, *Macbeth*, *Prometheus*, the *Orestes*, *Oedipus* belong to a class of poems which are more exalted than the others because they are unfolded on a sort of sacred mountain girt about by a certain mystery. This is what, in the hierarchy of the masterpieces, places *Hamlet* incontestably above *Othello*, for instance, although *Othello* is as passionately, as profoundly and, doubtless, more normally human. They owe to this mountain which carries them between heaven and earth the best part of their sombre and sublime power. Now, if we examine the formation of this mountain, we become aware that the elements which compose it are borrowed from a variable and arbitrary supernaturalism; it is a "beyond" of a contestable character and appearance, which are religious or superstitious, transitory, therefore, or local. But—and this it is that gives it a place apart among the four or five great dramatic poems of the world—in *King Lear* there is no supernaturalism proper. The gods,

THE MEASURE OF THE HOURS

the inhabitants of the great imaginary worlds do not meddle with the action; fatality itself is here quite inward, is no more than passion run mad; and yet the immense drama unravels its five acts on a summit as high, as overladen with spells, poetry and unwonted anxieties as though all the traditional forces of heaven and hell had vied in ardour to superstruct its peaks. The absurdity of the original anecdote (all the great masterpieces, being intended to represent typical actions of a necessarily far-fetched exclusive and excessive character, are founded on a more or less absurd anecdote) disappears in the sublime magnificence of the height at which it is developed. Study more closely the structure of that summit: it is formed solely of enormous human strata, of gigantic blocks of passion, of reason, of general and almost familiar sentiments, overthrown, heaped up, superimposed by an awful tempest, but one profoundly suited to all that is most human in human nature.

That is why *King Lear* remains the youngest of the great tragic works, the only one which time has not withered. It needs an effort of our good-will, a forgetting of our condition and of our present certainties for us to be sincerely and wholly stirred by the spectacle of *Hamlet*, *Macbeth* or *Oedipus*. On the other hand, the wrath, the roars of pain, the prodigious curses of the old man, of the outraged father seem to issue from our modern hearts and brains; they rise up under our own sky; and, in respect of all the profound truths that form the spiritual and sentimental atmosphere of our planet, there is nothing essential to be added to them, nothing to be withdrawn from them. Were Shakspeare to return among us upon earth, he could no longer write *Hamlet* or *Macbeth*. He would feel that the main august and gloomy ideas upon which those poems rest would no longer carry them, whereas he would not need to alter a situation nor a line in *King Lear*.

V

The youngest, the most unchangeable of tragedies is also the most organically lyrical dramatic poem that was ever realised, the only one in the world in which the magnificence of the language does not once impair the probability, the naturalness of the dialogue. There is not a poet but knows that it is almost impossible on the stage to ally beautiful images with natural expression. There is no denying it: no scene in the mightiest tragedy or in the most hackneyed comedy, as Alfred de Vigny said, is ever more than a conversation between two or three people who have met to talk of their affairs. They have therefore to talk; and, in order to give us that which is the most necessary illusion on the stage, the illusion of reality, they must depart as little as possible from the language employed in everyday life. But, in this rather elementary life, we hardly ever express in words

THE MEASURE OF THE HOURS

anything that is brilliant or profound in our inner existence. If our habitual thoughts mingle with great and beautiful spectacles, with the highest mysteries of nature, they remain within ourselves in a latent condition, in a condition of dreams, of ideas, of mute feelings which, at the very most, betray themselves sometimes by a word, a phrase nobler or truer than those of our probable and usual conversation. Now, the drama being able to express hardly anything that would not be expressed in life, it follows that all the higher part of existence remains unformulated there, lest it should shatter the indispensable illusion. The poet has therefore to choose: he will be lyrical or merely eloquent, but unreal (and this is the mistake of our classical tragedies, of the plays of Victor Hugo and of almost all the French and German romanticists, a few scenes of Goethe excepted), or else he will be natural, but dry, prosaic and dull. Shakspeare did not escape the dangers of this choice. In *Romeo and Juliet*, for instance, and in most of his historical plays, he pours forth into rhetoric and incessantly sacrifices to the splendour, to the abundance of his metaphors the imperious, essential precision and commonplace of every speech and cue.

VI

On the other hand, in his great masterpieces he makes no mistake; but the very manner in which he surmounts the difficulty reveals all the gravity of the problem. He achieves his end only with the aid of a sort of subterfuge to which he always resorts. As it seems to be accepted that a hero who expresses his inner life in all its magnificence cannot remain probable and human on the stage except on condition that he be represented as mad in real life (for it is understood that here the mad alone express that hidden life), Shakspeare systematically unsettles the reason of his protagonists and thus opens the dike that held captive the swollen lyrical flood. Henceforward, he speaks freely by their mouths; and beauty invades the stage without fearing lest it be told that it is out of place. Henceforward, also, the lyricism of his great works is more or less high, more or less wide in proportion to the madness of his hero. Thus it is intermittent and restrained in *Macbeth* and *Othello*, because the hallucinations of the Thane of Cawdor and the rages of the Moor of Venice are no more than passional crises; it is slow and pensive in *Hamlet*, because the madness of the Prince of Denmark is torpid and meditative; but no otherwhere does it overflow as in *King Lear*; torrential, uninterrupted and irresistible, hurling together, in immense and miraculous images, the oceans, the forests, the tempests and the stars, because the magnificent insanity of the dispossessed and desperate old king extends from the first scene to the very last.

THE INTELLIGENCE OF THE FLOWERS

I

I WISH merely to recall here a few facts known to every botanist. I have made not a single discovery and my modest contribution is confined to a few elementary observations. I need hardly say that I have no intention of reviewing all the proofs of intelligence which the plants give us. These proofs are innumerable and continual, especially among the flowers, in which the effort of vegetable life towards light and understanding is concentrated.

Though there be plants and flowers that are awkward or unlucky, there is none that is wholly devoid of wisdom and ingenuity. All exert themselves to accomplish their work, all have the magnificent ambition to overrun and conquer the surface of the globe by endlessly multiplying that form of existence which they represent. To attain this object, they have, because of the law that chains them to the soil, to overcome difficulties much greater than those opposed to the increase of the animals. And therefore the majority of them have recourse to combinations, to a machinery, to traps which, in regard to such matters as mechanism, ballistics, aerial navigation and the observation of insects, have often anticipated the inventions and acquirements of man.

II

It would be superfluous once more to trace the picture of the great systems of floral fertilisation: the play of stamens and pistil, the seduction of perfumes, the appeal of harmonious and dazzling colours, the concoction of nectar, which is absolutely useless to the flower and is manufactured only to attract and retain the liberator from without, the messenger of love—bee, humble-bee, fly, butterfly or moth—that is to bring to the flower the kiss of the distant, invisible, motionless lover. . . .

This vegetable world, which to us appears so placid, so resigned, in which all seems acquiescence, silence, obedience, meditation, is, on the contrary, that in which impatience, the revolt against destiny are the most vehement and stubborn. The essential organ, the nutrient organ of the plant, its root, attaches it indissolubly to the soil. If it be difficult to discover among the great laws that oppress us that which weighs heaviest upon our shoulders, in the case of the plant there is no doubt: it is the law that condemns it to immobility from its birth to its death. Therefore it knows better than we, who disseminate our efforts, against what first to rise in revolt. And the energy

THE MEASURE OF THE HOURS

of its fixed idea, mounting from the darkness of the roots to become organised and full-blown in the flower, is an incomparable spectacle. It exerts itself wholly with one sole aim: to escape above from the fatality below, to evade, to transgress the heavy and sombre law, to set itself free, to shatter the narrow sphere, to invent or invoke wings, to escape as far as it can, to conquer the space in which destiny encloses it, to approach another kingdom, to penetrate into a moving and active world. . . . Is the fact that it attains its object not as surprising as though we were to succeed in living outside the time which a different destiny assigns to us or in making our way into a universe freed from the weightiest laws of matter? We shall see that the flower sets man a prodigious example of insubmission, courage, perseverance and ingenuity. If we had applied to the removal of various necessities that crush us, such as pain, old age and death, one-half of the energy displayed by any little flower in our gardens, we may well believe that our lot would be very different from what it is.

III

This need of movement, this craving for space, among the greater number of plants, is manifested in both the flower and the fruit. It is easily explained in the fruit, or, in any case, discloses only a less complex experience and foresight. Contrary to that which takes place in the animal kingdom and because of the terrible law of absolute immobility, the chief and worst enemy of the seed is the paternal stock. We are in a strange world, where the parents, unable to move from place to place, know that they are condemned to starve or stifle their offspring. Every seed that falls at the foot of the tree or plant is either lost or doomed to sprout in wretchedness. Hence the immense effort to throw off the yoke and conquer space. Hence the marvellous systems of dissemination, of propulsion, of navigation of the air which we find on every side in the forest and the plain: among others, to mention, in passing, but a few of the most curious, the aerial screw or samara of the Maple; the bract of the Lime-tree; the flying-machine of the Thistle, the Dandelion and the Salsafy; the detonating springs of the Spurge; the extraordinary squirt of the Momordica; the hooks of the eriophilous plants; and a thousand other unexpected and astounding pieces of mechanism; for there is not, so to speak, a single seed but has invented for its sole use a complete method of escaping from the maternal shade.

It would, in fact, be impossible, if one had not practised a little botany, to believe the expenditure of imagination and genius in all the verdure that gladdens our eyes. Consider, for instance, the charming seed-pots of the Scarlet Pimpernel, the five valves of the Balsam, the five bursting capsules of the Geranium. Do not forget, upon occasion, to examine the common Poppy-head, which we find

THE MEASURE OF THE HOURS

at any herbalist's. This good, big head shelters a prudence and a foresight that deserve the highest praise. We know that it holds thousands of tiny black seeds. Its object is to scatter this seed as dexterously and to as great a distance as possible. If the capsule containing it were to split, to fall or to open underneath, the precious black dust would form but a useless heap at the foot of the maternal stalk. But its only outlet is through apertures contrived right at the top of the capsule, which, when ripe, bends over on its peduncle, sways like a censer at the least breath of wind and literally sows the seeds in space, with the very action employed by the sower.

Shall I speak of the seeds which provide for their dissemination by birds and which, to entice them, as in the case of the Mistletoe, the Juniper, the Mountain-ash, lurk inside a sweet husk? We see here displayed such a powerful reasoning faculty, such a remarkable understanding of final causes that we hardly dare dwell upon the subject, for fear of repeating the ingenious mistakes of Bernardin de Saint-Pierre. And yet the facts can be no otherwise explained. The sweet husk is of no more use to the seed than the nectar, which attracts the bees, is to the flower. The bird eats the fruit because it is sweet and, at the same time, swallows the seed, which is indigestible. He flies away and, soon after, ejects the seed in the same condition in which he has received it, but stripped of its case and ready to sprout far from the attendant dangers of its birthplace.

IV

But let us return to simpler contrivances. Pick a blade of grass by the roadside, from the first tuft that offers, and you will perceive an independent, indefatigable, unexpected little intelligence at work. Here, for instance, are two poor creeping plants which you have met a thousand times on your walks, for we find them in every spot, down to the most ungrateful corners to which a pinch of soil has strayed. They are two varieties of wild Lucern or Medick (*Medicago*), two ill weeds" in the humblest sense of the word. One bears a reddish flower, the other a little yellow ball the size of a pea. To see them crawling and hiding among the proud grasses, one would never suspect that, long before the illustrious geometrician and physician of Syracuse, they had discovered the Archimedean screw and endeavoured to apply it not to the raising of liquids, but to the art of flying. They lodge their seeds in light spirals with three or four convolutions, admirably constructed to delay their fall and, consequently, with the help of the wind, to prolong their journey through the air. One of them, the yellow, has even improved upon the apparatus of the red by furnishing the edges of the spiral with a double row of points, with the evident intention of hooking it, on its passage, to either the clothes of the pedestrians or the fleece of the animals. It

THE MEASURE OF THE HOURS

clearly hopes to add the advantages of eriophily—that is to say the dissemination of seed by sheep, goats, rabbits and so on—to those of anemophily, or dissemination by the wind.

The most touching side of this great effort is its futility. The poor red and yellow Lucerns have blundered. Their remarkable screws are of no use to them: they could act only if they fell from a certain height, from the top of some lofty tree or tall Graminea; but, constructed as they are on the level of the grass, they have hardly taken a quarter of a turn before already they touch the ground. We have here a curious instance of the mistakes, the gropings, the experiments and the frequent little miscalculations of nature; for only those who have studied nature but very little will maintain that she never errs.

Let us observe, in passing, that other varieties of the Lucern (not to speak of the Clover, another papilionaceous *Leguminosa*, almost identical with that of which we are now speaking) have not adopted this flying apparatus, but keep to the primitive methods of the pod. In one of them, the *Medicago aurantiaca*, we very clearly perceive the transition from the twisted pod to the screw or spiral. Another variety, the *Medicago scutellata*, or Snail-medick, rounds its screw in the form of a ball. It would seem, therefore, that we are assisting at the stimulating spectacle of a sort of work of invention, at the attempts of a family that has not yet settled its destiny and is seeking for the best way of ensuring its future. Was it not perhaps, in the course of this search that, having been deceived in the spiral, the yellow Lucern added points or hooks to it, saying to itself, not unreasonably, that, since its leaves attract the sheep, it is inevitable and right that the sheep should assume the care of its progeny? And, lastly, is it not thanks to this new effort and to this happy thought that the Lucern with the yellow flowers is infinitely more widely distributed than its sturdier cousin whose flowers are red?

V

It is not only in the seed or the flower, but in the whole plant, leaves, stalks and roots, that we discover, if we stoop for a moment over their humble work, many traces of a prudent and quick intelligence. Think of the magnificent struggle towards the light of the thwarted branches, or the ingenious and courageous strife of trees in danger. As for myself, I shall never forget the admirable example of heroism given me the other day in Provence, in the wild and delightful gorges of the Loup, all fragrant with violets, by a huge centenarian Laurel-tree. It was easy to read on its twisted and, so to speak, writhing trunk the whole drama of its hard and tenacious life. A bird or the wind, masters of destiny both, had carried the seed to the flank of the rock, which was as perpendicular as an iron curtain; and

THE MEASURE OF THE HOURS

the tree was born there, two hundred yards above the torrent, inaccessible and solitary, among the burning and barren stones. From the first hour, it had sent its blind roots on a long and painful search for precarious water and soil. But this was only the hereditary care of a species that knows the aridity of the South. The young stem had to solve a much graver and more unexpected problem: it started from a vertical plane, so that its top, instead of rising towards the sky, bent down over the gulf. It was obliged, therefore, notwithstanding the increasing weight of its branches, to correct the first flight, stubbornly to bend its disconcerted trunk in the form of an elbow close to the rock and thus, like a swimmer who throws back his head, by means of an incessant will, tension and contraction to hold its heavy crown of leaves straight up into the sky.

Thenceforward, all the preoccupations, all the energy, all the free and conscious genius of the plant had centred around that vital knot. The monstrous, hypertrophied elbow revealed, one by one, the successive solitudes of a kind of thought that knew how to profit by the warnings which it received from the rains and the storms. Year by year, the leafy dome grew heavier, with no other care than to spread itself out in the light and heat, while a hidden canker gnawed deep into the tragic arm that supported it in space. Then, obeying I know not what order of the instinct, two stout roots, two fibrous cables, issuing from the trunk at more than two feet above the elbow, had come to moor it to the granite wall. Had they really been evoked by the tree's distress or were they perhaps waiting providently, from the first day, for the acute hour of danger, in order to increase the value of their assistance? Was it only a happy accident? What human eye will ever assist at these silent dramas, which are all too long for our short lives?²

VI

Among the vegetals that give the most striking proofs of intelligence and initiative, the plants which might be described as "animated" or "sentient" deserve to be studied in detail. I will do no more than recall the delightful nervous terrors of the Sensitive-plant, the shrinking *Mimosa* with which we are all acquainted. There are other herbs endowed with spontaneous movements that are not so well known, notably the *Hedysareae*, among which the *Hedysarum gyrans*, or Moving-plant, acts in a very restless and surprising fashion. This little Leguminosa, which is a native of Bengal, but often cultivated in our hothouses, performs a sort of perpetual and intricate dance in honour of the light. Its leaves are divided into three folioles, one wide and terminal, the two others narrow and planted at the base of the first. Each of these leaflets is animated with a different movement of its own. They live in a state of rhythmical, al-

THE MEASURE OF THE HOURS

most chronometrical and continuous agitation. They are so sensitive to light that their dance flags or quickens according as the clouds veil or uncover that corner of the sky which they contemplate. They are, as we see, real photometers; and this long before Crook's discovery of the natural otheoscopes.

VII

But these plants, to which should be added the *Droseras*, the *Dionaeas* and many others, are nervous plants that already go a little beyond the mysterious and probably imaginary ridge that separates the vegetable from the animal kingdom. It is not necessary to seek so high; and we find as much intelligence and almost as much visible spontaneity at the other end of the world which we are considering, in the low-lying places where the plant is hardly distinct from clay or stone. We have here the fabulous class of the *Cryptogamia*, which can be studied only under the microscope, for which reason we will pass it by in silence, although the work of the sporules of the Mushrooms, Ferns and Horse-tails is incomparable in its delicacy and ingenuity. But, among the aquatic plants, the inhabitants of the original ooze and mud, we can see less secret marvels performed. As the fertilisation of their flowers cannot be accomplished underwater, each of them has thought out a different system to allow of the dry dissemination of the pollen. Thus, the *Zosteras*, that is to say, the common Sea-wrack with which we stuff our beds, carefully enclose their flower in a regular diving-bell; and the Water-lilies send theirs to blossom on the surface of the pond, supporting and feeding it at the top of an endless stalk, which lengthens as the level of the water rises. The *Villersia nymphoides*, having no expanding stalk, simply lets its flowers go: they rise to the surface and burst like bubbles. The *Trapa natans*, or Water-caltrop, supplies them with a sort of inflated tumour: they shoot up and open. Then, when the fertilisation is accomplished, the air in the tumour is replaced by a mucilaginous fluid, heavier than the water, and the whole apparatus sinks back again to the slime, where the fruits ripen.

The system of the *Utricularia* is even more complicated. M. Henri Bocquillon describes it in his *Vie des Plantes*:

“These plants, which are common in ponds, ditches, pools and the puddles of peat-bogs, are not visible in winter, when they lie on the mud. Their long, slim, trailing stalk is furnished with leaves reduced to ramified filaments. At the axilla of the leaves thus transformed, we see a sort of little pyriform pocket with an aperture in its pointed upper end. This aperture has a valve, which can be opened only from the outside inwards; its edges are provided with ramified hairs; the inside of the pocket is covered with other little secretory hairs which give it the appearance of velvet. When the moment of efflorescence has come, the axillary utricles fill with air: the more this air tends to escape, the more tightly it closes the

THE MEASURE OF THE HOURS

valve. The result is that it imparts a great specific buoyancy to the plant and carries it to the surface of the water. Not till then do those charming little yellow flowers come into blossom, resembling quaint little mouths with more or less swollen lips and palates streaked with orange or rubiginous lines. During the months of June, July and August, they display their fresh colours gracefully above the muddy water, amid the vegetable decay around them. But fertilisation has been effected, the fruit develops, all things play a different part: the ambient water presses upon the valve of the utricles, forces it in, rushes into the cavity, weighs down the plant and compels it to descend to the mud again."

Is it not interesting to see thus gathered in this immemorial little apparatus some of the most fruitful and recent of human inventions: the play of valves or plugs, the pressure of fluids and air, the Archimedean principle studied and turned to account? As the author whom we have just quoted observes, "The engineer who first attached a rafting apparatus to a sunk ship little thought that a similar process had been in use for thousands of years." In a world which we believe unconscious and destitute of intelligence, we begin by imagining that the least of our ideas creates new combinations and relations. When we come to look into things more closely, it appears infinitely probable that it is impossible for us to create anything whatsoever. We are the last comers on this earth, we simply find what has always existed and, like astonished children, we travel again the road which life had travelled before us. When all is said, it is very natural and comforting that this should be so. But we will return to this point.

VIII

We must not leave the aquatic plants without briefly mentioning the life of the most romantic of them all: the legendary *Vallisneria*, an hydrocharad whose nuptials form the most tragic episode in the love-history of the flowers. The *Vallisneria* is a rather insignificant herb, possessing none of the strange grace of the Water-lily or of certain submersed verdant plants. But it seems as though nature had delighted in giving it a beautiful idea. Its whole existence is spent at the bottom of the water, in a sort of half-slumber, until the moment of the wedding-hour comes, when it aspires to a new life. Then the female plant slowly uncoils the long spiral of its peduncle, rises, emerges and floats and blossoms on the surface of the pond. From a neighbouring stem, the male flowers, which see it through the sunlit water, rise in their turn, full of hope, towards the one that rocks, that awaits them, that calls them to a fairer world. But, when they have come halfway, they feel themselves suddenly held back: their stalk, the very source of their life, is too short; they will never reach the abode of light, the only spot in which the union of the stamens and the pistil can be achieved! . . .

THE MEASURE OF THE HOURS

Is there any more cruel inadvertence or ordeal in nature? Picture the tragedy of that longing, the inaccessible so nearly attained, the transparent fatality, the impossible with not a visible obstacle! It would be insoluble, like our own tragedy upon this earth, were it not that an unexpected element is mingled with it. Did the males foresee the disillusion to which they would be subjected? One thing is certain, that they have locked up in their hearts a bubble of air, even as we lock up in our souls a thought of desperate deliverance. It is as though they hesitated for a moment; then, with a magnificent effort, the finest, the most supernatural that I know of in all the pageantry of the insects and the flowers, in order to rise to happiness they deliberately break the bond that attaches them to life. They tear themselves from their peduncle and, with an incomparable flight, amid bubbles of gladness, their petals dart up and break the surface of the water. Wounded to death, but radiant and free, they float for a moment beside their heedless brides and the union is accomplished, whereupon the victims drift away to perish, while the wife, already a mother, closes her corolla, in which lives their last breath, rolls up her spiral and descends to the depths, there to ripen the fruit of the heroic kiss.

Must we spoil this charming picture, which is strictly accurate, but seen from the side of the light, by looking at it also from that of the shadow? Why not? There are sometimes on the shady side truths quite as interesting as those on the bright. This delightful tragedy is perfect only when we consider the intelligence and the aspirations of the species. But, when we observe individuals, we shall often see them act awkwardly and in the wrong way in this ideal plan. At one time, the male flowers will ascend to the surface when there are not yet any pistilled flowers near. At another, when the low water would permit them easily to join their companions, they will nevertheless mechanically and to no purpose break their stalks. We here once more establish the fact that all genius lies in the species, in life or in nature, whereas the individual is nearly always stupid. In man alone does a real emulation exist between the two intelligences, a more and more precise, more and more active tendency towards a sort of equilibrium which is the great secret of our future.

IX

The parasitic plants, again, present curious and crafty spectacles, as in the case of the astonishing *Cuscuta*, commonly called the Dodder. It has no leaves; and no sooner has its stalk attained a few inches in length than it voluntarily abandons its roots to twine about its chosen victim, into which it digs its suckers. Thenceforth, it lives exclusively upon its prey. Its perspicacity is not to be deceived; it will refuse any support that does not please it and will go some distance,

if necessary, in search of the stem of Hemp, Hop, Lucern or Flax that suits its temperament and its taste.

This *Cuscuta* naturally calls our attention to the Creepers, which have very remarkable habits and which deserve a word to themselves. Those of us who have lived a little in the country have often had occasion to admire the instinct, the sort of power of vision, that directs the tendrils of the Virginian Creeper or the *Convolvulus* towards the handle of a rake or spade resting against a wall. Move the rake and, the next day, the tendril will have turned completely round and found it again. Schopenhauer, in his treatise *Ueber den Willen in der Natur*, in the chapter devoted to the physiology of plants, recapitulates on this point and on many others a host of observations and experiments which it would take too long to set out here. I therefore refer the reader to this chapter, where he will find numerous sources and references marked out for him. Need I add that, in the past sixty or seventy years, these sources have been strangely multiplied and that, besides, the subject is almost inexhaustible?

Among so many different inventions, artifices and precautions, let us mention also, for instance, the foresight displayed by the *Hyo-seris radiata*, or Starry Swine's-succory, a little yellow-flowered plant, not unlike the Dandelion and often found on the walls of the Riviera. In order to ensure both the dissemination and the stability of its race, it bears at one and the same time two kinds of seeds: the first are easily detached and are furnished with wings wherewith to abandon themselves to the wind, while the others have no wings, remain captive in the inflorescence and are set free only when the latter is decomposed.

The case of the *Xanthium spinosum*, or Spiny Xanthium, shows us how well-conceived and effective certain systems of dissemination can be. This Xanthium is a hideous weed, bristling with barbaric prickles. Not long ago, it was unknown in Western Europe and no one, naturally, had dreamt of acclimatising it. It owes its conquests to the hooks which finish off the capsules of its fruits and which cling to the fleece of the animals. A native of Russia, it came to us in bales of wool imported from the depths of the Muscovite steppes; and one might follow on the map the stages of this great emigrant which has annexed a new world.

The *Silene Italica*, or Italian Catchfly, a simple little white flower, found in abundance under the olive-trees, has set its thought working in another direction. Apparently very timorous, very susceptible, to avoid the visits of importunate and indelicate insects it furnishes its stalks with glandular hairs, whence oozes a viscid fluid in which the parasites are caught with such success that the peasants of the South use the plant as a fly-catcher in their houses. Certain kinds of Catchflies, moreover, have ingeniously simplified the system. Dreading the ants in particular, they discovered that it was

THE MEASURE OF THE HOURS

enough, in order to prevent them from passing, to place a wide viscid ring under the node of each stalk. This is exactly what our gardeners do when they draw a circle of tar around the trunk of the apple-trees to stop the ascent of the caterpillars.

This leads to the study of the defensive means employed by the plants. In an excellent popular work, *Les Plantes originales*, to which I refer the reader who wishes for fuller details, M. Henri Coupin examines some of these quaint and startling weapons. We have first the stimulating question of the thorns, concerning which M. Lothelier, a student at the Sorbonne, has made a number of interesting experiments, resulting in the conclusion that shade and damp tend to suppress the prickly parts of the plants. On the other hand, whenever the place in which it grows is dry and burnt by the sun, the plant bristles and multiplies its spikes, as though it felt that, as almost the sole survivor among the rocks or in the hot sand, it is called upon to make a mighty effort to redouble its defences against an enemy that no longer has a choice of victims to prey upon. It is a remarkable fact, moreover, that, when cultivated by man, most of the thorny plants gradually lay aside their weapons, leaving the care of their safety to the supernatural protector who has adopted them in his fenced grounds.³

Certain plants, among others the *Boraginea*, supply the place of thorns with very hard bristles. Others, such as the Nettle, add poison. Others, the Geranium, the Mint, the Rue, steep themselves in powerful odours to keep off the animals. But the strangest are those which defend themselves mechanically. I will mention only the Horse-tail, which surrounds itself with a veritable armour of microscopic *silicae*. Moreover, almost all the Gramineae, in order to discourage the gluttony of the slugs and snails, add lime to their tissues.

X

Before broaching the study of the complicated forms of apparatus rendered necessary by cross-fertilisation, among the thousands of nuptial ceremonies that prevail in our gardens let us mention the ingenious ideas of some very simple flowers, in which the grooms and brides are born, love and die in the same corolla. The typical system is well enough known: the stamens, or male organs, generally frail and numerous, are grouped around the robust and patient pistil. But the disposition, the form, the habits of these organs vary in every flower, as though nature had a thought that cannot yet become settled, or an imagination that makes it a point of honour never to repeat itself. Often the pollen, when ripe, falls quite naturally from the top of the stamens upon the pistil; but very often, also, pistil and stamens are of the same height, or the latter are too far away, or the pistil is twice as tall as they. Then come endless efforts to succeed in

THE MEASURE OF THE HOURS

meeting. Sometimes, as in the Nettle, the stamens, at the bottom of the corolla, stand covering on their stalk: at the moment of fertilisation, the stalk straightens out like a spring and the anther, or pollen-mass, that tops it shoots a cloud of dust over the stigma. Sometimes, as in the Barberry, whose nuptials can be accomplished only in the bright hours of a cloudless day, the stamens, far removed from the pistil, are kept against the sides of the flower by the weight of their moist glands: the sun appears and evaporates the fluid and the unballasted stamens dart upon the stigma. Elsewhere are different things again: thus, in the Primroses, the females are by turns longer and shorter than the males: In the Lily, the Tulip and other flowers, the too lanky bride does what she can to gather and fix the pollen. But the most original and fantastic system is that of the Rue (*Ruta graveolens*), a rather evil-smelling medicinal herb of the ill-famed emmenagogic tribe. The peaceful and docile stamens, drawn up in a circle around the fat, squat pistil, wait expectant in the yellow corolla. At the conjugal hour, obeying the command of the female, which apparently gives a sort of call by name, one of the males approaches and touches the stigma. Then come the third, the fifth, the seventh, the ninth male, until the whole row of odd numbers has rendered service. Next, in the even ranks, comes the turn of the second, the fourth, the sixth and so on. Here in verity is love to order! This flower which knows how to count appears to me so extraordinary that I at first refused to believe the botanists; and I was determined more than once to test its numerical sense before accepting it. I have ascertained positively that it but seldom makes a mistake.

It is superfluous to multiply these instances. A stroll in the woods or fields will allow any one to make a thousand observations in this direction, each quite as curious as those related by the botanists. But, before closing this chapter, I would mention one more flower: not that it displays any extraordinary imagination, but because of the delightful and easily-perceptible grace of its movement of love. I allude to the *Nigella Damascena*, or Fennel-flower, whose folk-names are charming: Love-in-a-mist, Devil-in-a-bush, Ragged-lady; so many happy and touching efforts of popular poetry to describe a little flower that pleases it. This plant is found in a wild state in the South, by the roadside and under the olive-trees, and is often cultivated in the North in old-fashioned gardens. Its blossom is a pale blue, simple as a floweret in a primitive painting, and the "Venus' locks" or "ragged locks" that give the Ragged-lady its popular name in France are the light, tenuous, tangled leaves that surround the corolla with a "bush" of misty verdure. At the source of the flower, the five extremely long pistils stand close-grouped in the centre of the azure crown, like five queens clad in green gowns, haughty and inaccessible. Around them crowd hopelessly the innumerable throng of their lovers, the stamens, which do not come up to their knees. And now, in the heart of this palace of sapphires and tur-

THE MEASURE OF THE HOURS

quoises, in the gladness of the summer days, begins the drama without words or catastrophe which one might expect, the drama of powerless, useless, motionless waiting. But the hours pass that are the flower's years: its brilliancy fades, its petals fall and the pride of the great queens seems at last to bend under the weight of life. At a given moment, as though obeying the secret and irresistible command of love, which deems the proof to have lasted long enough, with a concerted and symmetrical movement, comparable with the harmonious parabolas of a five-fold jet of water, they all together bend backwards, stoop and gracefully cull the golden dust of the nuptial kiss on the lips of their humble lovers.

XI

The unexpected abounds here, as we see. A great volume might be written on the intelligence of the plants, even as *Romanes* wrote one on animal intelligence. But this sketch has no pretension to become a manual of that kind; and I wish only to call attention to a few interesting events that happen beside us in this world wherein we think ourselves, a little too vaingloriously, privileged. These events are not selected, but taken, by way of instances, as the random result of observation and circumstance. I propose, however, in these short notes, to concern myself above all with the flower, for it is in the flower that the greatest marvels shine forth. I set aside, for the moment, the carnivorous flowers, *Droseras*, *Nepenthes* and the rest, which approach the animal kingdom and would demand a special and expansive study, in order to devote myself to the true flower, the flower proper, which is believed to be motionless, insentient, passive and inanimate.

To separate facts from theories, let us speak of the flower as though all that it has realised had been foreseen and conceived in the manner of men. We shall see later how much we must leave to it, how much take away from it. For the present, let it take the stage alone, like a splendid princess endowed with reason and will. There is no denying that it appears to be provided with both; and to deprive it of either we should have to resort to very obscure hypotheses. It is there, then, motionless on its stalk, sheltering in a dazzling tabernacle the reproductive organs of the plant. Apparently, it has but to allow the mysterious union of the stamens and pistil to be accomplished in this tabernacle of love. And many flowers do so consent. But to many others there is propounded, big with awful threats, the normally insoluble problem of cross-fertilisation. As the result of what numberless and immemorial experiments did they observe that self-fertilisation—that is the fertilisation of the stigma by the pollen falling from the anthers that surround it in the same corolla—rapidly induces the degeneration of the species? They have ob-

THE MEASURE OF THE HOURS

served nothing, we are told, nor profited by any experience. The force of things quite simply and gradually eliminated the seeds and plants weakened by self-fertilisation. Soon only those survived which, through some anomaly, such as the exaggerated length of the pistil, rendering it inaccessible to the anthers, were prevented from fertilising themselves. These exceptions alone endured, through a thousand revolutions; heredity finally determined the work of chance; and the normal type disappeared.

XII

We shall see presently what light these explanations throw. For the moment, let us stroll into the garden or the field, to study more closely two or three curious inventions of the genius of the flower. And already, without going far from the house, we have here, frequented by the bees, a sweet-scented cluster inhabited by a most skilled mechanic. There is no one, even among the least countrified, but knows the good Sage. It is an unpretending *Labiata* and bears a very modest flower, which opens violently, like a hungry mouth, to snap the rays of the sun in passing. For that matter, it presents a large number of varieties, not all of which—this is a curious detail—have adopted or carried to the same pitch of perfection the system of fertilisation which we are about to examine. But I am concerned here only with the most common Sage, that which, at this moment, as though to celebrate spring's passage, covers with violet draperies all the walls of my terraces of olive-trees. I assure you that the balconies of the great marble palaces that await the kings were never more luxuriously, more happily, more fragrantly adorned. One seems to catch the very perfumes of the light of the sun at its hottest, when noon-day strikes. . . .

To come to details, the stigma, or female organ, of the flower is contained in the upper lip, which forms a sort of hood, in which are also the two stamens, or male organs. To prevent these from fertilising the stigma which shares the same nuptial tent, this stigma is twice as long as they, so that they have no hope of reaching it. Moreover, in order to avoid any accident, the flower has made itself proteandrous, that is to say, the stamens ripen before the pistil, so that, when the female is fit to conceive, the males have already disappeared. It is necessary, therefore, that an external force should intervene to accomplish the union by carrying a foreign pollen to the abandoned stigma. A certain number of flowers, the anemophilous flowers, leave this care to the wind. But the Sage—and this is the more general case—is entomophilous, that is to say, it loves insects and relies upon their collaboration alone. Still, it is quite aware, for it knows many things, that it lives in a world where it is best to expect no sympathy, no charitable aid. It does not waste time, therefore, in

making useless appeals to the courtesy of the bee. The bee, like all that struggles against death in this world of ours, exists only for herself and for her kind and is in no way concerned to render a service to the flowers that feed her. How shall she be obliged, in spite of herself, or at least unconsciously, to fulfil her matrimonial office? Observe the wonderful love-trap contrived by the Sage: right at the back of its tent of violet silk, it distils a few drops of nectar; this is the bait. But, barring the access to the sugary fluid, stand two parallel stalks, somewhat similar to the uprights of a Dutch drawbridge. Right at the top of each stalk is a great sack, the anther, overflowing with pollen; at the bottom, two smaller sacks serve as a counterpoise. When the bee enters the flower, in order to reach the nectar she has to push the small sacks with her head. The two stalks, which turn on an axis, at once topple over and the upper anthers come down and touch the sides of the insect, whom they cover with fertilising dust. No sooner has the bee departed than the springy pivots fly back and replace the mechanism in its first position; and all is ready to repeat the work at the next visit.

However, this is only the first half of the play: the sequel is enacted in another scene. In a neighbouring flower, whose stamens have just withered, enters upon the stage the pistil that awaits the pollen. It issues slowly from the hood, lengthens out, stoops, curves down, becomes forked so as, in its turn, to bar the entrance to the tent. On its way to the nectar, the head of the bee passes freely under the hanging fork, which, however, grazes her back and sides exactly at the spots touched by the stamens. The two-cleft stigma greedily absorbs the silvery dust; and the impregnation is accomplished. It is easy, for that matter, by introducing a straw or the end of a match, to set the apparatus going and to take stock of the striking and marvellous combination and precision of all its movements.

The varieties of the Sage are very many—they number about five hundred—and I will spare you the majority of their scientific names, which are not always pretty: *Salvia pratensis*, *officinalis* (our Garden Sage), *Horminum Horminoides*, *glutinosa*, *Sclarea*, Romeri, *azurea*, *Pitcheri*, *spleridens* (the magnificent Sage of our baskets) and so on. There is not, perhaps, one but has modified some detail of the machinery which we have just examined. A few—and this, I think, is a doubtful improvement—have doubled and sometimes trebled the length of the pistil, so that it not only emerges from the hood, but makes a wide plume-like curve in front of the entrance to the flower. They thus avoid the just-possible danger of the fertilisation of the stigma by the anthers dwelling in the same hood; but, on the other hand, it may happen, if the protenandry be not strict, that the insect, on leaving the flower, deposits on the stigma the pollen of the very anthers with which the stigma cohabits. Others in the movement of the lever, make the anthers diverge farther apart so as to strike the sides of the animal with greater precision. Others, lastly, have not

THE MEASURE OF THE HOURS

succeeded in arranging and adjusting every part of the mechanism. I find, for instance, not far from my violet Sage, near the well, under a cluster of Oleanders, a family of white flowers tinted with pale lilac which have no suggestion or trace of a lever. The stamens and the stigma are heaped up promiscuously in the middle of the corolla. All seems left to chance and disorganised.

I have no doubt that it would be possible, to any one collecting the very numerous varieties of this *Labiata*, to reconstruct the whole history, to follow all the stages of the invention, from the primitive disorder of the white Sage under my eyes to the latest improvements of the *Salvia pratensis*. What conclusion are we to draw? Is the system still in the experimental stage among the aromatic tribe? Has it not yet left the period, of models and “trial trips,” as in the case of the Archimedean screw in the Saintfoin family? Has the excellence of the automatic lever not yet been unanimously admitted? Can it be, then, that everything is not unchangeable and preestablished; and are they still discussing and experimenting in this world which we believe to be fatally, organically regular?⁴

XIII

Be this as it may, the flower of most varieties of the Sage presents an attractive solution of the great problem of cross-fertilisation. But, even as, among men, a new invention is at once taken up, simplified, improved by a host of small indefatigable seekers, so, in the world of what we may call mechanical flowers, the patent of the Sage has been elaborated and in many details strangely perfected. A pretty general *Scrophularinea*, the common Lousewort, or Red-rattle (*Pedicularis sylvatica*), which you must surely have noticed in the shady parts of small woods and heaths, has introduced some extremely ingenious modifications. The shape of the corolla is almost similar to that of the Sage; the stigma and the two anthers are all three contained in the upper hood. Only the little moist tip of the pistil protrudes from the hood, while the anthers remain captive. In this silky tabernacle, therefore, the organs of the two sexes are very close together and even in immediate contact; nevertheless, thanks to an enactment quite different from that of the Sage, self-fertilisation is made absolutely impossible. The anthers, in fact, form two sacks filled with powder; each of the sacks has only one opening and they are juxtaposed in such a way that the openings coincide and mutually close each other. They are forcibly kept inside the hood, on their curved, springy stalks, by a sort of teeth. The bee or humble-bee that enters the flower to sip its nectar necessarily pushes these teeth aside; and the sacks are no sooner set free than they fly up, are flung outside and alight upon the back of the insect.

THE MEASURE OF THE HOURS

But the genius and foresight of the flower go farther than this. As Hermann Müller, who was the first to make a complete study of the wonderful mechanism of the Lousewort, observes (I am quoting from a summary):

“If the stamens struck the insect while preserving their relative positions, not a grain of pollen would leave them, because their orifices reciprocally close each other. But a contrivance which is as simple as it is ingenious overcomes the difficulty. The lower lip of the corolla, instead of being symmetrical and horizontal, is irregular and slanting, so that one side of it is higher by a few millimetres than the other. The humble-bee resting upon it must herself necessarily stand in a sloping position. The result is that her head strikes first one and then the other of the projections of the corolla. Therefore the releasing of the stamens also takes place successively; and, one after the other, their orifices, now freed, strike the insect and sprinkle her with fertilising dust.

“When the humble-bee next passes to another flower, she inevitably fertilises it, because—and I have purposely omitted this detail—what she meets first of all, when thrusting her head into the entrance to the corolla, is the stigma, which grazes her just at the spot where she is about, the moment after, to be struck by the stamens, the exact spot where she has already been touched by the stamens of the flower which she has last left.”

XIV

These instances might be multiplied indefinitely; every flower has its idea, its system, its acquired experience which it turns to advantage. When we examine closely their little inventions, their diverse methods, we are reminded of those enthralling exhibitions of machine-tools, of machines for making machinery, in which the mechanical genius of man reveals all its resources. But our mechanical genius dates from yesterday, whereas floral mechanism has been at work for thousands of years. When the flowers made their appearance upon our earth, there were no models around them which they could imitate; they had to derive everything from within themselves. At the period when we had not gone beyond the club, the bow and the flail; in the comparatively recent days when we conceived the spinning-wheel, the pulley, the tackle, the ram; at the time—it was last year, so to speak—when our masterpieces were the catapult, the clock and the weaving-loom, the Sage had contrived the uprights and counterweights of its lever of precision and the Lousewort its sacks closed up as though for a scientific experiment, the successive releasing of its springs and the combination of its inclined planes. Who, say a hundred years ago, dreamt of the properties of the screw which the Maple and the Lime-tree have been turning to use since the birth of the trees? When shall we succeed in building a parachute or a flying-machine as rigid, as light, as subtle and as safe as that of the Dandelion? When shall we discover the secret of cutting in so frail a fabric as the silk of the petals a spring as powerful as

THE MEASURE OF THE HOURS

that which projects into space the golden pollen of the Spanish Broom? As for the Momordica, or Squirting Cucumber, whose name I mentioned at the beginning of this little study, who shall tell us the mystery of its miraculous strength? Do you know the Momordica? It is a humble *Cucurbitacea*, common enough along the Mediterranean coast. Its prickly fruit, which resembles a small cucumber, is endowed with inexplicable vitality and energy. You have but to touch it, at the moment of its maturity, and it suddenly quits its peduncle by means of a convulsive contraction and shoots through the hole produced by the wrench, mingled with numerous seeds, a mucilaginous stream of such wonderful intensity that it carries the seed to four or five yards' distance from the natal plant. The action is as extraordinary, in proportion, as though we were to succeed in emptying ourselves with a single spasmodic movement and in precipitating all our organs, our viscera and our blood to a distance of half a mile from our skin and skeleton.

A large number of seeds besides have ballistic methods and employ sources of energy that are more or less unknown to us. Remember, for instance, the explosions of the Colza and the Heath. But one of the great masters of vegetable artillery is the Spurge. The Spurge is an *Euphorbiacea* of our climes, a tall and fairly ornamental "weed," which often exceeds the height of a man. I have a branch of Spurge on my table at this moment steeped in a glass of water. It has trifid, greenish berries, which contain the seeds. From time to time, one of these berries bursts with a loud report; and the seeds, gifted with a prodigious initial velocity, strike the furniture and the walls on every side. If one of them hits your face, you feel as though you had been stung by an insect, so extraordinary is the penetrating force of these tiny seeds, each no larger than a pin's head. Examine the berry, look for the springs that give it life: you shall not find the secret of this force, which is as invisible as that of our nerves.

The Spanish Broom (*Spartium junceum*) has not only pods, but flowers fitted with springs. You may have remarked the wonderful plant. It is the proudest representative of this powerful family of the Brooms. Greedy of life, poor, sober, robust, rejecting no soil, no trial, it forms (along the paths and in the mountains of the South) huge, tufted balls, sometimes three yards high, which, between May and June, are covered with a magnificent bloom of pure gold, whose perfumes, mingling with those of its habitual neighbour, the Honey-suckle, spread under the fury of a fierce sun delights that are not to be described save by evoking celestial dews, Elysian springs, cool streams and starry transparencies in the hollow of azure grottoes. . . .

The flower of this Broom, like that of all the papilionaceous *Leguminosae*, resembles the flowers of the Peas of our gardens; and its lower petals, shaped like the beak of a galley, contain hermetically the stamens and the pistil. So long as it is not ripe, the bee who ex-

THE MEASURE OF THE HOURS

plores it finds it impenetrable. But, as soon as the moment of puberty arrives for the captive bride and grooms, the beak bends under the weight of the insect that rests upon it; and the golden chamber bursts voluptuously, hurling with violence and afar, over the visitor, over the flowers around, a cloud of luminous dust, which a broad petal, shaped like a penthouse, casts down upon the stigma to be impregnated.

XV

Let us leave the seeds and return to the flowers. As I have said, one could prolong indefinitely the list of their ingenious inventions. I refer those who might wish to study these problems thoroughly to the works of Christian Konrad Sprengel, who was the first, in 1793, in his curious volume, *Das entdeckte Geheimniss der Natur im Bau und in der Befruchtung der Blumen*, to analyse the functions of the different organs in the Orchids; next, to the books of Charles Darwin, Dr. Hermann Müller of Lippstadt, Hildebrand, Delpino the Italian, Sir William Hooker, Robert Brown and many others.

We shall find the most perfect and the most harmonious manifestations of vegetable intelligence among the Orchids. In these writhing and eccentric flowers, the genius of the plant touches its extreme point and with an unusual fire pierces the wall that separates the kingdoms. For that matter, this name of Orchid must not be allowed to mislead us or make us believe that we have here to do only with rare and precious flowers, with those hothouse queens which seem to claim the care of the goldsmith rather than the gardener. Our native wild flora, which comprises all our modest "weeds," numbers more than twenty-five species of Orchids, including just the most ingenious and complicated. It is these which Charles Darwin studied in his book, *On the Various Contrivances by which Orchids are fertilised by Insects*, which is the wonderful history of the most heroic efforts of the soul of the flower. It is out of the question that I should here, in a few lines, summarise that abundant and fairylike biography. Nevertheless, since we are on the subject of the intelligence of flowers, it is necessary that we should give some idea of the methods and the mental habits of that which excels all the others in the art of compelling the bee or the butterfly to do exactly what it wishes, in the prescribed form and time.

XVI

It is not easy to explain without diagrams the extraordinarily complex mechanism of the Orchid. Nevertheless, I will try to give a

THE MEASURE OF THE HOURS

sufficient idea of it with the aid of more or less approximate comparisons, while avoiding as far as possible the use of technical terms such as *retinaculum*, *labellum*, *rostellum* and the rest, which evoke no precise image in the minds of persons unfamiliar with botany.

Let us take one of the most widely distributed Orchids in our regions, the *Orchis maculata*, for instance, or rather, because it is a little larger and therefore more easily observed, the *Orchis latifolia*, the Marsh Orchid, commonly known as the Meadow-rocket. It is a perennial plant and grows to a height of an inch or more. It is fairly common in the woods and damp meadows and it bears a thyrses of little pink flowers which blossom in May and June. The typical flower of our Orchids represents pretty closely the fantastic and yawning mouth of a Chinese dragon. The lower lip, which is very long and which hangs in the form of a jagged or dentate apron, serves as a landing-place for the insect. The upper lip rounds into a sort of hood, which shelters the essential organs; while, at the back of the flower, beside the peduncle, there falls a kind of spur or long, pointed horn, which contains the nectar. In most flowers, the stigma, or female organ, is a more or less viscid little tuft which, at the end of a frail stalk, patiently awaits the coming of the pollen. In the Orchid, this traditional installation has become irrecognisable. At the back of the mouth, in the place occupied in the throat by the uvula, are two closely-welded stigmas, above which rises a third stigma modified into an extraordinary organ. At its top, it carries a sort of little pouch, or, more correctly, a sort of stoup, which is called the *rostellum*. This stoup is full of a viscid fluid in which soak two tiny balls whence issue two short stalks laden at their upper extremity with a packet of grains of pollen carefully tied up.

Let us now see what happens when an insect enters the flower. She lands on the lower lip, outspread to receive her, and, attracted by the scent of the nectar, seeks to reach the horn that contains it, right at the back. But the passage is purposely very narrow; and the insect's head, as she advances, necessarily strikes the stoup. The latter, sensitive to the least shock, is at once ruptured along a convenient line and lays bare the two little balls steeped in the viscid fluid. These, coming into immediate contact with the visitor's skull, fasten to it and become firmly stuck to it, so that, when the insect leaves the flower, she carries them away and, with them, the two stalks which rise from them and which end in the packets of tied-up pollen. We therefore have the insect capped with two straight, bottle-shaped horns. The unconscious artisan of a difficult work now visits a neighbouring flower. If her horns remained stiff, they would simply strike with their pollen-masses the other pollen-masses soaking in the vigilant stoup and no event would spring from the pollen mingling with pollen. But here the genius, the experience and the foresight of the Orchid become apparent. The Orchid has minutely calculated the time needed for the insect to suck the nectar and repair

THE MEASURE OF THE HOURS

to the next flower; and it has ascertained that this requires, on an average, thirty seconds. We have seen that the packets of pollen are carried on two short stalks inserted into the viscid balls. Now at the point of insertion there is, under each stalk, a small membranous disc, whose only function is, at the end of thirty seconds, to contract and throw forward the stalks, causing them to curve and describe an arc of ninety degrees. This is the result of a fresh calculation, not of time, on the occasion, but of space. The two horns of pollen that cap the nuptial messenger are now horizontal and point in front of her head, so that, when she enters the next flower, they will just strike the two welded stigmas under the pendent stoup.

This is not all and the genius of the Orchid has not yet expended all its foresight. The stigma which receives the blow of the packet is coated with a viscid substance. If this substance were as powerfully adhesive as that contained in the stoup, the pollen-masses, after their stalks were broken, would stick to it and remain fixed to it whole; and their destiny would be ended. This must not be; it is important that the chances of the pollen should not be exhausted in a single venture, but rather that they should be multiplied to the greatest possible extent. The flower that counts the seconds and measures the lines is a chemist to boot and distils two sorts of gums: one extremely clinging, hardening as soon as it touches the air, to glue the pollen-horns to the insect's head; the other greatly lenified, for the work of the stigma. This latter is just prehensile enough slightly to unfasten or loosen the tenuous and elastic threads with which the grains of pollen are tied up. Some of these grains cling to it, but the pollinic mass is not destroyed; and, when the insect visits other flowers, she will continue her fertilising labours almost indefinitely.

Have I expounded the whole miracle? No; I have still to call attention to many a neglected detail: among others, to the movement of the little stoup, which, after its membrane has been ruptured to unmask the viscid balls, immediately lifts up its lower rim in order to keep in good condition, in the sticky fluid, the packet of pollen which the insect may not have carried off. We should also note the very curiously combined divergence of the pollinic stalks on the head of the insect, as well as certain chemical precautions common to all plants; for the experiments made quite recently by M. Gaston Bonnier seem to prove that every flower, in order to preserve its species intact, secretes poisons that destroy or sterilise any foreign pollen. This is about all that we see; but here, as in all things, the real, the great miracle begins where our power of vision ends.

XVII

I have just this moment found, in an untilled corner of the olive-

THE MEASURE OF THE HOURS

yard, a splendid sprig of *Loroglossum hircinum*, a variety which, for I know not what reason (perhaps it is very rare in England), Darwin omitted to study. It is certainly the most remarkable, the most fantastic, the most astounding of all our native Orchids. If it were of the size of the American Orchids, one could declare that there is no more fanciful plant in existence. Imagine a thyrses, like that of the Hyacinth, but twice as tall. It is symmetrically adorned with ill-favoured, three-cornered flowers, of a greenish white stippled with pale violet. The lower petal, embellished at its source with bronzed caruncles, huge mustachios and sinister-looking lilac buboes, stretches out interminably, madly, unreally, in the shape of a corkscrew riband of the colour assumed by a drowned corpse after a month's immersion in the river. From the whole, which conjures up the idea of the most fearsome maladies and seems to blossom in some vague land of ironical nightmares and witcheries, there issues a potent and abominable stench as of a poisoned goat, which spreads afar and reveals the presence of the monster. I am pointing to and describing this nauseating Orchid because it is fairly common in France, is easily recognised and adapts itself very well, by reason of its height and the distinctness of its organs, to any experiments that one might wish to make. We have only, in fact, to introduce the tip of a match into the flower and to push it carefully to the bottom of the nectary, in order, with the naked eye, to witness all the successive revolutions of the process of fertilisation. Grazed in passing, the pouch or *rostellum* sinks down, exposing the little viscid disc (the *Loroglossum* has only one) that supports the two pollen-stalks. As soon as this disc violently grips the end of the wood, the two cells that contain the pollen-balls open longitudinally; and, when the match is withdrawn, its tip is firmly capped with two stiff, diverging horns, ending in two golden balls. Unfortunately, we do not here, as in the experiment with the *Orchis latifolia*, enjoy the charming spectacle offered by the gradual and precise inclination of the two horns. Why are they not lowered? We have but to introduce the capped match into a neighbouring nectary to ascertain that this movement would be superfluous, the flower being much larger than that of the *Orchis maculata* or *latifolia* and the nectar-horn arranged in such a way that, when the insect laden with the pollen-masses enters it, they just reach the level of the stigma to be fertilised.

Let us add that it is important to the success of the experiment to select a flower that is quite ripe. We do not know when the flower is ripe; but the insect and the flower itself know, for the flower does not invite its necessary guests, by offering them a drop of nectar, until the moment comes when all its apparatus is ready to work.

XVIII

This is the basis of the system of fertilisation adopted by the Orchid of our climes. But each species, every family modifies and improves the details in accordance with its particular experience, psychology and convenience. The *Orchis* or *Anacamptis pyramidalis*, for instance, which is one of the most intelligent, has added to its lower lip or labellum two little ridges which guide the proboscis of the insect to the nectar and compel her to accomplish exactly what is expected of her. Darwin very justly compares this ingenious accessory with the little instrument for guiding a thread into the fine eye of a needle. Here is another interesting improvement: the two little balls that carry the pollen-stalks and soak in the stoup are replaced by a single viscid disc, shaped like a saddle. If, following the road to be taken by the insect's proboscis, we insert the point of a needle or a bristle into the flower, we very plainly perceive the advantages of this simpler and more practical arrangement. As the bristle touches the stoup, the latter is ruptured in a symmetrical line and uncovers the saddle-formed disc, which at once becomes attached to the bristle. Withdraw the bristle smartly and you will just have time to catch the pretty action of the saddle, which, seated on the bristle or needle, curls its two flaps inwards, so as to embrace the object that supports it. The purpose of this movement is to strengthen the adhesive power of the saddle and, above all, to ensure with greater precision than in the *Orchis latifolia* the indispensable divergence of the pollen-stalks. As soon as the saddle has curled round the bristle and as the pollen-stalks planted in it, drawn apart by its contraction, are forced to diverge, the second movement of the stalks begins and they bend towards the tip of the bristle, in the same manner as in the Orchid which we have already studied. The two movements combined are performed in thirty to thirty-four seconds.

XIX

Is it not exactly in this manner, by means of trifles, of successive overhaulings and retouches, that human inventions proceed? We have all, in the latest of our mechanical industries, followed the tiny, but constant improvements in the sparking, the carburation, the clutch and the speed-gear. It would really seem as though ideas came to the flowers in the same way as to us. The flowers grope in the same darkness, encounter the same obstacles, the same ill-will, in the same unknown. They have the same laws, the same disillusion, the same slow and difficult triumphs. They would appear to possess our patience, our perseverance, our self-love, the same varied and diversified intelligence, almost the same hopes and the,

THE MEASURE OF THE HOURS

same ideals. They struggle, like ourselves, against a great indifferent force that ends by assisting them. Their inventive imagination not only follows the same prudent and minute methods, the same tiring, narrow and winding little paths: it also has unexpected leaps and bounds that suddenly fix definitely an uncertain discovery. It is thus that a family of great inventors among the Orchids, a strange and rich American family, that of the *Catasetidae*, thanks to a bold inspiration, abruptly altered a number of habits that doubtless appeared to it too primitive. First of all, the separation of the sexes is absolute: each has its particular flower. Next, the *pollinium*, or mass or packet of pollen, no longer dips its stalk in a stoup full of gum, there awaiting, a little inertly and, in any case, without initiative, the lucky accident that is to fix it on the insect's head. It is bent back on a powerful spring, in a sort of cell. Nothing attracts the insect specially in the direction of this cell. Nor have the proud *Catasetidae* reckoned, like the common Orchid, on this or that movement of the visitor: a guided and precise movement, if you wish, but nevertheless a contingent movement. No, the insect no longer enters a flower endowed with an admirable mechanism: she enters an animated and literally sensitive flower. Hardly has she pitched upon the magnificent outer court of copper-coloured silk before long and nervous feelers, which she cannot avoid touching, carry the alarm all over the edifice. Forthwith the cell is torn asunder in which the pollen-mass, divided into two packets, is held captive on its bent-back pedicel, which is supported on a huge viscid disc. Abruptly released, the pedicel straightens itself like a spring, dragging with it the two packets of pollen and the viscid disc, which are violently projected outside. In consequence of a curious ballistic calculation, the disc is always flung first and strikes the insect, to whom it adheres. She, stunned by the blow, has but one thought: to leave the aggressive corolla with all speed and take refuge in a neighbouring flower. This is all that the American Orchid wanted.

XX

Shall I describe also the curious and practical simplifications introduced into the general system by another family of exotic Orchids, the *Cypripedae*? Let us continue to bear in mind the circumvolutions of human inventions: we have here an amusing counterproof. A fitter, in the engine-room, a preparator, a pupil, in the laboratory, says, one day, to his principal: "Suppose we tried to do just the opposite? Suppose we reversed the movement, suppose we inverted the mixture of the fluids?" The experiment is tried; and suddenly from the unknown issues the unexpected.

One could easily believe the *Cypripedae* to have held similar conversations among themselves. We all know the *Cypripedium*, or

THE MEASURE OF THE HOURS

Ladies'-slipper: with its enormous shoe-shaped chin, its crabbed and venomous air, it is the most characteristic flower of our hothouses, the one that seems to us the typical Orchid, so to speak. The Cypripedium has bravely suppressed all the complicated and delicate apparatus of the springy pollen-masses, the diverging stalks, the viscid discs, the cunning gums and the rest. Its clog-like chin and a barren, shield-shaped anther bar the entrance in such a manner as to compel the insect to pass its proboscis over two little heaps of pollen. But this is not the important point: the wholly unexpected and abnormal thing is that, contrary to what we have observed in all the other species, it is no longer the stigma, the female organ that is viscid, but the pollen itself, whose grains, instead of being pulverulent, are covered with a coat so glutinous that it can be stretched and drawn into threads. What are the advantages and the drawbacks of this new arrangement? It is to be feared that the pollen carried off by the insect may adhere to any object other than the stigma; on the other hand, the stigma is dispensed from secreting the fluid destined to sterilise every foreign pollen. In any case, this problem would demand a special study. In the same way, there are patents whose usefulness we do not grasp at once.

XXI

To have done with this strange tribe of the Orchids, it remains for us to say a few words on an auxiliary organ that sets the whole mechanism going: I mean the nectary, which, for that matter, has been the object, on the part of the genius of the species, of enquiries, attempts and experiments as intelligent and as varied as those which are incessantly modifying the economy of the essential organs.

The nectary, as we have seen, is, in principle, a sort of spur, of long, pointed horn that opens right at the bottom of the flower, beside the peduncle, and acts more or less as a counterpoise to the corolla. It contains a sugary liquid, the nectar, which serves as food for butterflies, beetles and other insects and which is turned into honey by the bee. Its business, therefore, is to attract the indispensable guests. It is adapted to their size, their habits, their tastes; it is always arranged in such a way that they cannot introduce or withdraw their proboscis without scrupulously and successively performing all the rights prescribed by the organic laws of the flower.

We already know enough of the fantastic character and imagination of the Orchids to foresee that here, as elsewhere—and even more than elsewhere, for the more supple organ lends itself to this more readily—their inventive, practical, observant and groping spirit has given itself free scope. One of them, for instance, the *Sarcanthus teretifolius*, probably failing in its endeavour to elaborate a viscid fluid that should harden quickly enough to stick the bundle of

pollen to the insect's head, has overcome the difficulty by delaying the visitor's proboscis as long as possible in the narrow passages leading to the nectar. The labyrinth which it has laid out is so complicated that Bauer, Darwin's skilful draughtsman, had to admit himself beaten and gave up the attempt to reproduce it.

There are some which, starting on the excellent principle that every simplification is an improvement, have boldly suppressed the nectar-horn. They have replaced it by certain fleshy, fantastic and evidently succulent excrescences which are nibbled by the insects. Is it necessary to add that these excrescences are always placed in such a manner that the guest who feasts on them must inevitably set all the pollen-machinery in movement?

XXII

But, without lingering over a thousand very various little artifices, let us end these fairy stories by studying the enticements of the *Coryanthes macrantha*. Truly, we no longer know with exactly what sort of being we here have to do. The astounding Orchid has contrived this: its lower lip or *labellum* forms a sort of bucket, into which drops of almost pure water, secreted by two horns situated overhead, fall continually; when this bucket is half full, the water flows away on one side by a spout or gutter. All this hydraulic installation is very remarkable in itself; but here is where the alarming, I might almost say the diabolical side of the combination begins. The liquid which is secreted by the horns and which accumulates in the satin basin is not nectar and is in no way intended to attract the insects: it has a much more delicate function in the really machiavellian plan of this strange flower. The artless insects are invited by the sugary perfumes diffused by the fleshy excrescences of which I spoke above to walk into the trap. These excrescences are above the cup, in a sort of chamber to which two lateral openings give access. The big visiting bee—the flower, being enormous, allures hardly any but the heaviest *Hymenopterae*, as though the others experienced a certain shame at entering such vast and sumptuous halls—the big bee begins to nibble the savoury caruncles. If she were alone, she would go away quietly, after finishing her meal, without even grazing the bucket of water, the stigma and the pollen; and none of that which is required would take place. But the sapient Orchid observes the life that moves around it. It knows that the bees form an innumerable, greedy and busy people, that they come out by thousands in the sunny hours, that a perfume has but to quiver like a kiss on the threshold of an opening flower for them to hasten in a crowd to the banquet prepared under the nuptial tent. We therefore have two or three looters in the sugary chamber: the space is scanty, the walls slippery, the guests ill-mannered. They crowd and hustle one another.

THE MEASURE OF THE HOURS

er to such good purpose that one of them always ends by falling into the bucket that awaits her beneath the treacherous repast. She there finds an unexpected bath, conscientiously wets her bright, diaphanous wings and, despite immense efforts, cannot succeed in resuming her flight. This is where the astute flower lies in wait for her. There is but one opening through which she can leave the magic bucket: the spout that acts as a waste-pipe for the overflow of the reservoir. It is just wide enough to allow of the passage of the insect, whose back touches first the sticky surface of the stigma and then the viscid glands of the pollen-masses that await her along the vault. She thus escapes, laden with the adhesive dust, and enters a neighbouring flower, where the tragedy of the banquet, the hustling, the fall, the bath and the escape is reenacted and perforce brings the imported pollen into contact with the greedy stigma.

Here, then, we have a flower that knows and plays upon the passions of insects. Nor can it be pretended that all these are only so many more or less romantic interpretations: no, the facts have been precisely and scientifically observed and it is impossible to explain the use and arrangement of the flower's different organs in any other way. We must accept the evidence as it stands. This incredible and efficacious artifice is the more surprising inasmuch as it does not here tend to satisfy the immediate and urgent need to eat that sharpens the dullest wits; it has only a distant ideal in view: the propagation of the species.

But why, we shall be asked, these fantastic complications which end only by increasing the dangers of chance? Let us not hasten to give judgment and reply. We know nothing of the reasons of the plant. Do we know what obstacles the flower encounters in the direction of logic and simplicity? Do we know thoroughly a single one of the organic laws of its existence and its growth? One watching us from the height of Mars or Venus, as we exert ourselves to achieve the conquest of the air, might, in his turn, ask:

“Why those shapeless and monstrous machines, those balloons, those air-ships, those parachutes, when it were so easy to copy the birds and to supply the arms with a pair of all-sufficing wings?”

XXIII

To these proofs of intelligence, man's somewhat puerile vanity opposes the traditional objection: yes, they create marvels, but those marvels remain eternally the same. Each species, each variety has its system and, from generation to generation, introduces no perceptible improvement. It is true that, since we have been observing them—that is to say, during the past fifty years—we have not seen the *Coryanthes macrantha* or the *Catasetidae* perfect their trap: this is all that we can say; and it is really not enough. Have we as much as at-

THE MEASURE OF THE HOURS

tempted the most elementary experiments; and do we know what the successive generations of our astonishing bathing Orchid might do in a century's time, if placed in different surroundings, among insects to which it was not accustomed? Besides, the names which we give to the orders, species and varieties end by deceiving ourselves; and we thus create imaginary types which we believe to be fixed, whereas they are probably only the representatives of one and the same flower, which continues to modify its organs slowly in accordance with slow circumstances.

The flowers came upon our earth before the insects; they had, therefore, when the latter appeared, to adapt an entirely new system of machinery to the habits of these unexpected collaborators. This geologically incontestable fact alone, amid all that which we do not know, is enough to establish evolution; and does not this somewhat vague word mean, after all, adaptation, modification, intelligent progress?

It would be easy, moreover, without appealing to this prehistoric event, to bring together a large number of facts which would show that the faculty of adaptation and intelligent progress is not reserved exclusively for the human race. Without returning to the detailed chapters which I have devoted to this subject in *The Life of the Bee*, I will simply recall two or three topical details which are there mentioned. The bees, for instance, invented the hive. In the wild and primitive state and in their country of origin, they work in the open air. It was the uncertainty, the inclemency of our northern seasons that gave them the idea of seeking a shelter in hollow trees or a hole in the rocks. This ingenious idea restored to the work of looting and to the care of the eggs the thousands of bees stationed around the combs to maintain the necessary heat. It is not uncommon, especially in the South, during exceptionally mild summers, to find them reverting to the tropical manners of their ancestors.⁵

Another fact: when transported to Australia or California, our black bee completely alters her habits. After one or two years, finding that summer is perpetual and flowers for ever abundant, she will live from day to day, content to gather the honey and pollen indispensable for the day's consumption; and, her recent and thoughtful observation triumphing over hereditary experience, she will cease to make provision for her winter. Buchner mentions an analogous fact, which also proves the bees' adaptation to circumstances, not slow, secular, unconscious and fatal, but immediate and intelligent: in Barbados, the bees whose hives are in the midst of the refineries, where they find sugar in plenty during the whole year, will entirely abandon their visits to the flowers.

Let us lastly recall the amusing contradiction which the bees gave to two learned English entomologists, Kirkby and Spence:

"Show us," said these, "a single case in which, under stress of circumstances, the bees have had the idea of substituting clay or

THE MEASURE OF THE HOURS

mortar for wax and propolis and we will admit their reasoning faculties.”

Hardly had they expressed this somewhat arbitrary wish, when another naturalist, Andrew Knight, having coated the bark of certain trees with a sort of cement made of wax and turpentine, observed that his bees entirely ceased to gather propolis and employed only this new and unknown substance, which they found prepared in abundance in the neighbourhood of their home. Moreover, in the practice of apiculture, when pollen is scarce, the bee-keeper has but to place a few handfuls of flour at their disposal for them at once to understand that this can serve the same purpose and be turned to the same use as the dust of the anthers, although its taste, smell and colour are absolutely different.

What I have just said, in the matter of the bees, might, I think, *mutatis mutandis*, be confirmed in the kingdom of the flowers. I have referred above to my humble experiments in the wonderful evolutionary efforts of the numerous varieties of the Sage. And a curious study by Babinet on the cereals tells us that certain plants, when transported far from their habitual climate, observe the new circumstances and avail themselves of them, exactly as the bees do. Thus, in the hottest regions of Asia, Africa and America, where the winter does not kill it annually, our corn becomes again what it must have been at first, a perennial plant, like grass. It remains always green, multiplies by the root and no longer bears ears or grains. When, therefore, from its original and tropical country, it came to be acclimatised in our icy regions, it must have had to upset its habits and invent a new method of multiplication. As Babinet well says:

“The organism of the plant, thanks to an inconceivable miracle, seemed to foresee the need of passing through the grain state, lest it should perish completely during the severe season.”

XXIV

In any case, to destroy the objection which we mentioned above and which has caused us to travel so far from our immediate subject, it would be enough to establish one act of intelligent progress, were it but for a single occasion, outside mankind. But, apart from the pleasure which one takes in refuting an over-vain and out-of-date argument, how little importance, when all is said, attaches to this question of the personal intelligence of the flowers, the insects or the birds! Suppose that we say, speaking of the Orchid and the bee alike, that it is nature and not the plant or the insect that calculates, that combines, that adorns, invents and thinks: what interest can this distinction have for us? A much loftier question and one much wor-

THE MEASURE OF THE HOURS

thier of our eager attention towers over these details. What we have to do is to grasp the character, the quality, the habits and perhaps the object of the general intelligence whence emanate all the intelligent acts performed upon this earth. It is from this point of view that the study of those creatures—the ants and the bees, among others—in which, outside the human form, the proceedings and the ideal of that genius are most clearly manifested becomes one of the most curious that we can undertake. It is clear, after all that we have shown, that those tendencies, those intellectual methods must be at least as complex, as advanced, as startling in the Orchids as in the gregarious *Hymenopterae*. Let us add that a large number of the motives and a portion of the logic of these restless insects, so difficult of observation, still escape us, whereas we can grasp with ease all the silent motives, all the wise and stable arguments of the peaceful flower.

XXV

Now what do we observe, when we perceive nature (or the general intelligence or the universal genius: the name matters but little) at work in the Orchid world? Many things; and, to mention it only in passing, for the subject would offer facilities for a long study, we begin by ascertaining that her idea of beauty, of gladness, her methods of attraction, her aesthetic tastes are very near akin to our own. But no doubt it would be more correct to state that ours are congenial with hers. It is, in fact, very uncertain whether we have ever invented a beauty peculiar to ourselves. All our architectural, all our musical motives, all our harmonies of colour and light are borrowed directly from nature. Without calling upon the sea, the mountains, the skies, the night, the twilight, what might one not say, for instance, of the beauty of the trees? I speak not only of the tree considered in the forest, where it is one of the powers of the earth, perhaps the chief source of our instincts, of our sense of the universe, but of the tree in itself, the solitary tree, whose green old age is laden with a thousand seasons. Among those impressions which, without our knowing it, form the limpid hollow and perhaps the subsoil of happiness and calm of our whole existence, which of us does not preserve the recollection of a few fine trees? When a man has passed mid-life, when he has come to the end of the wondering period, when he has exhausted nigh all the sights that the art, the genius and the luxury of ages and men can offer, after experiencing and comparing many things he returns to very simple memories. They raise upon the purified horizon two or three innocent, invariable and refreshing images, which he would wish to carry away with him in his last sleep, if it be true that an image can pass the threshold that separates our two worlds. For myself, I can imagine no paradise nor af-

THE MEASURE OF THE HOURS

ter-life, however splendid it may be, in which a certain magnificent Oak would be out of place, or a certain Cypress, or a Parasol Pine of Florence or of a charming hermitage near my own house, any one of which affords to the passer-by a model of all the great movements of necessary resistance, of peaceful courage, of soaring, of gravity, of silent victory and of perseverance.

XXVI

But I am wandering too far afield: I intended only to remark, with reference to the flower, that nature, when she wishes to be beautiful, to please, to delight and to prove herself happy, does almost what we should do had we her treasures at our disposal. I know that, speaking thus, I am speaking a little like the bishop who was astonished that Providence always made the great streams flow close to the big cities; but it is difficult to look upon these things from any other than a human point of view. Let us, then, from this point of view, consider that we should know very few signs or expressions of happiness if we did not know the flower. In order well to judge of its power of gladness and beauty, one must live in a part of the country where it reigns undivided, such as the corner of Provence, between the Siagne and the Loup, in which I am writing these lines. Here, truly, the flower is the sole sovereign of the hills and valleys. The peasants have lost the habit of cultivating corn, as though they had now only to provide for the needs of a subtle race of mankind that lived on sweet fragrance and ambrosia. The fields form one great nosegay, which is incessantly renewed, and the perfumes that succeed one another seem to dance their rounds all through the azure year. Anemones, Gilliflowers, Mimosas, Violets, Pinks, Narcissuses, Hyacinths, Jonquils, Mignonette, Jasmine invade the days, the nights, the winter, summer, spring and autumn months. But the magnificent hour belongs to the Roses of May. Then, as far as the eye can see, from the slope of the hills to the hollow of the plains, between dikes of Vines and Olive-trees, they flow on every side like a stream of petals whence emerge the houses and the trees, a stream of the colour which we assign to youth, health and joy. The aroma, at once warm and refreshing, but above all spacious, that opens up the sky emanates, one would think, directly from the sources of beatitude. The roads, the paths are carved in the pulp of the flower, in the very substance of Eden. For the first time in one's life, one seems to have a satisfying vision of happiness.

XXVII

Still from our human point of view and persevering in the necessary illusion, let us add to our first remark one a little more extensive, a little less hazardous and perhaps big with consequences, namely, that the genius of the earth, which is probably that of the whole world, acts, in the vital struggle, exactly as a man would act. It employs the same methods, the same logic. It attains its aim by the same means that we would use: it gropes, it hesitates, it corrects itself time after time; it adds, it suppresses, it recognises and repairs its errors, as we should do in its place. It makes great efforts, it invents with difficulty and little by little, after the manner of the workmen and engineers in our workshops. It fights like ourselves against the heavy, huge and obscure mass of its being. It knows no more than we do whither it is going; it seeks and finds itself gradually. It has an ideal that is often confused, but one in which, nevertheless, we distinguish a host of great lines that rise towards a more ardent, complex, nervous and spiritual form of existence. Materially, it disposes of infinite resources, it knows the secret of prodigious forces of which we know nothing; but, intellectually, it appears strictly to occupy our sphere: we cannot prove that, hitherto, it has exceeded its limits; and, if it does not endeavour to take anything from beyond that sphere, does this not mean that there is nothing beyond it? Does it not mean that the methods of the human mind are the only possible methods, that man has not erred, that he is neither an exception nor a monster, but the being through whom pass, in whom are most intensely manifested the great volitions, the great desires of the universe?

XXVIII

The touchstones of our consciousness emerge slowly, grudgingly. Perhaps Plato's famous figure is no longer sufficient: I mean the cave with the wall above it whence the shadows of unknown men and objects are thrown into the cave below; but, if we tried to substitute a new and more exact image in its place, this would be hardly more consoling. Suppose Plato's cave enlarged. No ray of brightness ever enters it. With the exception of light and fire, it has been carefully supplied with all that our civilisation permits; and men have been imprisoned in it from their birth. They would not regret the light, having never seen it; they would not be blind, their eyes would not be dead, but, having nothing to look at, would probably become the most sensitive organ of touch.

In order to recognise ourselves in their actions, let us picture these wretches in their darkness, in the midst of the multitude of

THE MEASURE OF THE HOURS

unknown objects that surround them. What quaint mistakes, what incredible deviations, what astounding misinterpretations must needs occur! But how touching and often how ingenious would seem the use which they would make of things that had not been created for employment in the dark! How often would they guess aright? And how great would not be their stupefaction if, suddenly, by the light of day, they discovered the nature and the real object of utensils and furniture which they had accommodated as best they could to the uncertainties of the shade?

And yet their position seems simple and easy compared with our own. The mystery in which they crawl is limited. They are deprived of only one sense, whereas it is impossible to estimate the number of those in which we are lacking. The cause of their mistakes is one alone, whereas those of ours are countless.

Since we live in a cave of this sort, is it not interesting to prove that the power which has placed us there acts often and on some important points even as we act ourselves? Here we have a glimpse of light in our subterranean cave to show us that we have not been mistaken as to the use of every object to be found therein.

XXIX

We have long taken a rather foolish pride in thinking ourselves miraculous, unparalleled and marvellously incidental beings, probably fallen from another world, devoid of any certain ties with the rest of life and, in any case, endowed with an unusual, incomparable, monstrous faculty. It is greatly preferable to be less prodigious, for we have learnt that prodigies do not take long to disappear in the normal evolution of nature. It is much more consoling to observe that we follow the same road as the soul of this great world, that we have the same ideas, the same hopes, the same trials and—were it not for our specific dream of justice and pity—the same feelings. It is much more tranquilising to assure ourselves that, to better our lot, to utilise the forces, the occasions, the laws of matter, we employ methods exactly similar to those which it uses to conquer, enlighten and order its unsubjected, unconscious and unruly regions, that there are no other methods, that we are in the midst of truth and that we are in our right place and at home in this universe formed of unknown substances, whose thought, however, is not impenetrable and hostile, but analogous and apposite to our own.

If nature knew everything, if she were never mistaken, if, everywhere, in all her undertakings, she showed herself, at the first onset, perfect, impeccable, infallible, if she revealed in all things an intelligence immeasurably superior to our own, then there would be cause to fear and to lose courage. We should feel ourselves the victims and the prey of an extraneous power, which we should have no

THE MEASURE OF THE HOURS

hope of knowing or measuring. It is much better to be convinced that this power, at least from the intellectual point of view, is closely akin to our own. Our intelligence draws upon the same reserve as does that of nature. We belong to the same world, we are almost equals. We are associating not with inaccessible gods, but with veiled, yet fraternal volitions which it is our business to surprise and to direct.

XXX

It would not, I imagine, be very bold to maintain that there are not any more or less intelligent beings, but a scattered, general intelligence, a sort of universal fluid that penetrates diversely the organisms which it encounters according as they are good or bad conductors of the understanding. Man would then represent, until now, upon this earth, the mode of life that offered the least resistance to this fluid, which the religions called divine. Our nerves would be the threads along which this more subtle electricity would spread. The circumvolutions of our brain would, in a manner, form the induction-coil in which the force of the current would be multiplied; but this current would be of no other nature, would proceed from no other source than that which passes through the stone, the star, the flower or the animal.

But these are mysteries which it were somewhat idle to question, seeing that we do not yet possess the organ that could gather their reply. Let us be satisfied with having observed certain manifestations of this intelligence outside ourselves. All that we observe within ourselves is rightly open to suspicion: we are at once judge and suitor and we have too great an interest in peopling our world with magnificent illusions and hopes. But let the slightest external indication be dear and precious to us. Those which the flowers have just offered us are probably quite infinitesimal compared with what the mountains, the sea and the stars would tell us, could we surprise the secrets of their life. Nevertheless, they allow us to presume with greater confidence that the spirit which animates all things or emanates from them is of the same essence as that which animates our bodies. If this spirit resembles us, if we thus resemble it, if all that it contains is contained also within ourselves, if it employs our methods, if it has our habits, our preoccupations, our tendencies, our desires for better things, is it illogical for us to hope all that we do hope, instinctively, invincibly, seeing that it is almost certain that it hopes the same? Is it probable, when we find scattered through life so great a sum total of intelligence, that this life should make no work of intelligence, that is to say, should not pursue an aim of happiness, of perfection, of victory over that which we call evil, death, darkness, annihilation, but which is probably only the shadow of its face or its own

sleep?

PERFUMES

I

AFTER speaking at some length of the intelligence of the flowers, it will seem natural that we should say a word of their soul, which is their perfume. Unfortunately, here, as in the case of the soul of man, a perfume of another sphere, where reason bathes, we have at once to do with the unknowable. We are almost entirely unacquainted with the purpose of that zone of festive and invisibly magnificent air which the corollas shed around themselves. There is, in fact, a great doubt whether it serves chiefly to attract the insects. In the first place, many among the most sweet-scented of the flowers do not admit of cross-fertilisation, so that the visit of the butterfly or the bee is to them a matter of indifference or inconvenience. Next, that which attracts the insects is solely the pollen and the nectar, which, generally, have no perceptible odour. And thus we see them neglect the most deliciously perfumed flowers, such as the rose and the carnation, to besiege in crowds the flowers of the maple or the hazel-tree, whose aroma is, in a manner of speaking, null.

Let us, then, confess that we do not yet know in what respect perfumes are useful to the flower, even as we cannot tell why we ourselves perceive them. Indeed, of all our senses, that of smell is the most unexplained. It is evident that sight, hearing, touch and taste are indispensable to our animal existence. A long education alone teaches us the disinterested enjoyment of forms, colours and sounds. For that matter, our sense of smell also exercises important servile functions. It is the keeper of the air we breathe, the hygienist or chemist that watches carefully over the quality of the food offered for our consumption, any disagreeable emanation revealing the presence of suspicious or dangerous germs. But besides this practical mission it has another which corresponds with nothing at all. Perfumes are utterly useless to the needs of our physical life. When too violent or too lasting, they may even become detrimental to it. Nevertheless, we possess a faculty that revels in them and brings us the joyful tidings of them with as much enthusiasm and conviction as though it concerned the discovery of a delicious fruit or drink. This uselessness deserves our consideration. It must hide some fair secret. We have here the only occurrence in which nature procures us a gratuitous pleasure, a satisfaction that does not serve to adorn one of necessity's snares. Our scent is the only purely luxurious sense that she has granted us. Wherefore it seems almost foreign to our bodies, appears to be not very closely connected with our organism.

THE MEASURE OF THE HOURS

Is it an apparatus that is developing, or one that is wasting away; a somnolent, or an awakening faculty? Everything leads us to think that it is being evolved on even lines with our civilisation. The ancients interested themselves almost exclusively in the more brutal, the heavier, the more solid scents, so to speak: musk, benzoin, incense; and the fragrance of the flowers is very seldom mentioned in Greek and Latin poetry or in Hebrew literature. To-day, do we ever see our peasants, even at their longest periods of leisure, dream of smelling a violet or a rose? And is not this, on the other hand, the very first act of an inhabitant of our great cities who perceives a flower? There is, therefore, some ground for admitting that the sense of smell is the last-born of our senses, the only one, perhaps, that is not "in course of retrogression," to use the ponderous phrase of the biologists. This is a reason for making it our study, questioning it and cultivating its possibilities. Who shall tell the surprises which it would have in store for us if it equalled, for instance, the perfection of our sight, as it does in the case of the dog, which lives as much by the nose as by the eyes?

We have here an unexplored world. This mysterious sense, which, at first sight, appears almost foreign to our organism, becomes, perhaps, when more carefully considered, that which enters into it most intimately. Are we not, above all things, beings of the air? Is the air not for us the most absolutely and promptly indispensable element; and is not our smell just the one sense that perceives some parts of it? Perfumes, which are the jewels of that life-giving air, do not adorn it without good cause. It were not surprising if this luxury which we do not understand corresponded with something very profound and very essential and rather, as we have seen, with something that is not yet than with something that has ceased to be. It is very possible that this sense, the only one that is turned towards the future, is already discerning the most striking manifestations of a form or of a happy and salutary state of matter that is reserving many surprises for us.

Meanwhile, it has not yet reached beyond the stage of the more violent, the less subtle perceptions. Hardly does it so much as suspect, with the aid of the imagination, the profound and harmonious effluvia that evidently envelop the great spectacles of the atmosphere and the light. As we are on the point of distinguishing those of the rain and the twilight, why should we not one day succeed in recognising and fixing the scent of snow, of ice, of morning dew, of the first fruits of the dawn, of the twinkling of the stars; for everything must have its perfume, inconceivable, as yet, in space: even a moonbeam, a ripple of water, a hovering cloud, an azure smile of the sky. . . .

II

Chance or rather the choice of life has brought me back lately to the spot where almost all the perfumes of Europe are born and elaborated. It is, in point of fact, as every one knows, in the sun-swept and balmy region stretching from Cannes to Nice that the last hills and the last valleys of living and true flowers maintain an heroic struggle against the coarse chemical odours of Germany, which stand in exactly the same relation to nature's perfumes as do the painted woods and plains of a theatre to the woods and plains of the real country. Here the labourer's work is ruled by a sort of purely floral calendar, in which, in May and July, two adorable queens hold sway: the rose and the jasmine. Around these two sovereigns of the year, one the colour of the dawn, the other clad in white stars, defile in procession, from January to December, the violets, innumerable and prompt, the artless, marvel-eyed narcissuses, the clustering mimosas, the mignonette, the pink laden with precious spices, the imperious geranium, the tyrannically virginal orange-flower, the lavender, the Spanish broom, the too-potent tuberose and the acacia that resembles an orange caterpillar.

It is, at first, not a little disconcerting to see the great dull and heavy rustics, whom harsh necessity turns every elsewhere from the smiles of life, taking flowers so seriously, handling carefully those fragile ornaments of the earth, performing a task fit for a princess or a bee and bending under a weight of violets or jonquils. But the most striking impression is that of certain evenings or mornings in the season of the roses or the jasmine. It is as though the atmosphere of the earth had suddenly changed, as though it had made way for that of an infinitely happy planet, where perfumes are not, as here, fleeting, vague and precarious, but stable, spacious, full, permanent, generous, normal and inalienable.

III

Many writers, speaking of Grasse, have drawn the picture of that almost fairy-like industry which occupies the whole of a hard-working town, perched, like a sunlit hive, upon a mountain-side. They have told of the magnificent cartloads of roses shot upon the threshold of the smoking factories, the great halls in which the sorters literally wade through the flood of petals, the less cumbersome, but more precious arrival of the violets, tuberoses, acacias, jasmine, in wide baskets which the peasant-women carry nobly on their heads. Lastly, they have described the different processes whereby the flowers, each according to its character, are forced to yield to the crystal the marvellous secrets of their hearts. We know that some of

THE MEASURE OF THE HOURS

them, the roses, for instance, are accommodating and willing and give up their aroma with simplicity. They are heaped into huge boilers, tall as those of our locomotive engines, through which steam is made to pass. Little by little, their essential oil, more costly than a jelly of pearls, oozes drop by drop into a glass tube, no wider than a goose-quill at the bottom of the monstrous still, which resembles some mountain painfully giving birth to a tear of amber.

But the greater part of the flowers do not so easily allow their souls to be imprisoned. I will not, in the wake of so many others, speak here of the infinitely varied tortures inflicted upon them to force them at length to surrender the treasure which they desperately hide in the depth of their corollas. I will not enumerate the different processes of chemical extraction by means of petrol ether, sulphide of carbon and the rest. The great perfumers of Grasse, ever faithful to tradition, scorn these artificial and almost unfair methods, which wound the soul of the flower. It will suffice to give an idea of the executioner's cunning and the obstinacy of some of the victims, to recall the pangs of the enfleurage which certain flowers are made to endure before they break silence. The cold enfleurage is practised only upon the jonquil, the mignonette, the tuberose and the jasmine;⁶ and I may mention, in passing, that the scent of the jasmine is the only one that is inimitable, the only one that cannot be obtained by a cunning mixture of other odours. The torturer coats large plates of glass with a white fat of the thickness of two fingers and spreads on this bed of humiliating pain the flowers to be questioned. As the result of what hypocritical manoeuvres, of what unctuous promises does the fat obtain their irrevocable confidences? None can tell; but the fact remains that soon the too-trusting flowers have nothing more to lose. Forthwith, they are removed and flung away as rubbish; and, each morning, a new ingenuous heap takes their place on the insidious couch. These yield in their turn and undergo the same fate; others and yet others follow them; and it is not until the end of three months, that is after devouring ninety successive layers of flowers, that the unctuous ogre is completely surfeited and refuses to absorb the life and soul of any further victims. It now becomes a matter of making the wan miser disgorge; for the energy, to retain the absorbed treasure. This is achieved, not without difficulty. The fat has base passions which are its undoing. It is plied with alcohol, is intoxicated and ends by quitting its hold. The alcohol now possesses the mystery. No sooner has it the secrets in its custody than it too claims the right to impart them to none other, to keep them for itself alone. It is attacked in its turn, tortured, evaporated, condensed; and, after all these adventures, the liquid pearl, pure, essential, inexhaustible and almost imperishable, is at last gathered on a crystal blade.

¹ Cf. the essay entitled *In Praise of the Sword* in *The Double Garden*.—

THE MEASURE OF THE HOURS

Publishers' Note.

²Let us compare with this the act of intelligence of another root, whose exploits are related by Brandis in his *Ueber Leben und Polarität*. In penetrating into the earth, it had come upon an old boot-sole: in order to cross this obstacle, which, apparently, the root was the first of its kind to find upon its road, it subdivided itself into as many parts as there were holes left in the sole by the stitching needle; then, when the obstacle was overcome, it came together again and united all its divided radicles into a single homogeneous tap-root.

³Among the plants that have ceased to defend themselves, the most striking case is that of the Lettuce:

"In its wild state," says the author whom I have mentioned above, "if we break a stalk or a leaf, we see a white juice exude from it, the *latex*, a substance formed of different matters which vigorously defend the plant against the assaults of the slugs. On the other hand, in the cultivated species derived from the former, the *latex* is almost missing, for which reason the plant, to the despair of the gardeners, is no longer able to resist and allows the slugs to eat it."

It is nevertheless right to add that this *latex* is rarely lacking except in the young plants, whereas it becomes quite abundant when the Lettuce begins to "cabbage" and when it runs to seed. Now it is especially at the commencement of its life, at the budding of its first, tender leaves, that the plant needs to defend itself. One is inclined to think that the cultivated Lettuce loses its head a little, so to speak, and that it no longer knows exactly where it stands.

⁴For nearly four years, I have been engaged upon a series of experiments in the hybridisation of Sages, artificially fertilising (first taking the usual precautions against any interference of wind or insects) a variety of which the floral mechanism has reached a high state of perfection with the pollen of a very backward variety; and vice versa. My observations are not yet sufficiently numerous to permit me to give any details or conclusions here. Nevertheless, it already appears as if a general law were being evolved, namely that the backward Sage readily adopts the improvements of the more advanced variety, whereas the latter is not so prone to accept the defects of the first. This would tend to throw an interesting side-light upon the operations; the habits, the preferences, the tastes of nature at her best. But these experiments cannot possibly be completed in so short a period, because of the time lost in collecting the different varieties, of the numberless proofs and counter-proofs required and so on. It would be premature, therefore, as yet to draw the slightest conclusion from them.

⁵I had just written these lines, when M. E. L. Bouvier made a communication in the Academy of Science (*cf.* the report of the 7th of May, 1906) on the subject of two nidifications in the open air observed in Paris, one in a *Sophora Japonica*, the other in a chestnut-tree. The latter, which hung from a small branch furnished with two almost contiguous forks, was the more remarkable of the two, because of its evident and intelligent adaptation to particularly difficult circumstances.

"The bees," says M. de Parville, in his summary in the science-column of the Journal des *Débats* of the 31st of May, 1906, "built consolidating pillars and resorted to really remarkable artifices of protection and ended by transforming the two forks of the chest-nut-tree into a solid ceiling. An ingenious human being would certainly not have done so well.

"To protect themselves against the rain, they had installed fences, thickenings and blinds against the sun. One can have no idea of the perfection of the industry of the bees, except by observing the architecture of the two nidifications, now at the Museum."

⁶The violets resist the reduction of cold fat and the torture of fire has to be superadded. The lard, therefore, is heated in the water-bath until it approaches boiling-point. In consequence of this barbarous treatment, which recalls that in-

THE MEASURE OF THE HOURS

flicted upon the coiners of the middle ages, the modest and fragrant flowers that deck the roads in spring gradually lose the strength to keep their secret. They yield, they surrender, and their liquid executioner is not satiated until it has absorbed four times its own weight in petals, which causes the torture to be prolonged throughout the season in which the violets blossom under the olive-trees.
